EMPLOYMENT-UNEMPLOYMENT

THURSDAY, JULY 2, 1987

Congress of the United States, Joint Economic Committee,

Washington, DC.

The committee met, pursuant to notice, at 9:30 a.m., in room SD-628, Dirksen Senate Office Building, Hon. Paul S. Sarbanes (chairman of the committee) presiding.

Present: Senators Sarbanes and Melcher and Representative McMillan.

Also present: Richard F Kaufman, general counsel; and William Buechner, Dan Bond, Jim Klumpner, Paul Manchester, Dale Jahr, and Chris Frenze, professional staff members.

OPENING STATEMENT OF SENATOR SARBANES, CHAIRMAN

Senator SARBANES. The committee will come to order.

This morning the Joint Economic Committee will be conducting two hearings. The first will be the committee's regularly scheduled hearing on the employment and unemployment situation for June and we will hear from the Commissioner of Labor Statistics, Janet Norwood.

Following the conclusion of the hearing on the unemployment figures, the committee will resume its midyear review of the economy with a panel of two distinguished economists, Lawrence Chimerine, chief economist at Wharton Econometrics; and Alan Blinder, professor of economics at Princeton, who will focus on the economic outlook and the challenges facing economic policy.

I am pleased to welcome Commissioner Norwood this morning. On Monday, Commissioner Norwood was sworn in for her third term as head of the Bureau of Labor Statistics. It was a special occasion and I was pleased to be there.

Commissioner Norwood has had a long and distinguished career as a public servant and has brought superior leadership to the Bureau of Labor Statistics. As Commissioner of Labor Statistics for the last 8 years—and now we can look forward to an additional 4 years—and as Acting Commissioner for a year before she officially became Commissioner of Labor Statistics, Janet Norwood has unfailingly adhered to the highest standards of professional integrity. So, Commissioner, my congratulations and best wishes go to you as you begin your third term. We are pleased to have you again before the committee. We look forward to hearing from you and your associates this morning. STATEMENT OF HON. JANET L. NORWOOD, COMMISSIONER, BUREAU OF LABOR STATISTICS, DEPARTMENT OF LABOR, AC-COMPANIED BY THOMAS J. PLEWES, ASSOCIATE COMMISSION-ER, OFFICE OF EMPLOYMENT AND UNEMPLOYMENT STATIS-TICS; AND JOHN F. EARLY, ASSISTANT COMMISSIONER, DIVI-SION OF CONSUMER PRICES AND PRICE INDEXES

Mrs. Norwoop. Thank you very much, Mr. Chairman. I appreciate those kind words.

I have with me this morning on my right, John Early, who is our Assistant Commissioner for Consumer Prices; and on my left, Tom Plewes, who is in charge of our employment and unemployment programs.

It's always a pleasure to be here.

Unemployment declined in June, and employment showed little change. Following a very large increase from April to May, the labor force dropped in June. The overall unemployment rate, at 6 percent, and the civilian rate, at 6.1 percent, were each down 0.2 percentage point from May. Both rates have declined considerably over the past year.

Changes in the labor force of young adults—those 16 to 24 years of age—can be quite volatile during the summer months. So far this year, from April to June, the labor force for this group has risen by about 2.6 million before seasonal adjustment—considerably less than last year. Partly as a result of this development, after seasonal adjustment, joblessness among teenagers dropped from 17.7 to 15.9 percent in June.

The labor market experience of adult men during the summer months is far less volatile than for youngsters, and their unemployment rate was unchanged from May to June. However, at 5.5. percent, the June rate for adult men was well below the 6 percent which prevailed at the end of last year. The jobless rate for adult women declined from 5.4 percent in May to 6.2 percent in June. Employment for this group has advanced strongly in 1987. Their employment-population ratio held at a record high of 53.2 percent in June, and the jobless rate for adult women declined in June to the lowest level in 13 years.

Nonfarm payroll employment, as measured by our business survey, changed very little in May and in June, after increasing an average of 250,000 per month from January to April. Employment in the service-producing sector, growing by only 100,000 from May to June, has slowed from the pace of previous months. In fact, in the last 2 months, employment in this sector has grown at only half the rate registered in the year.

Employment in the goods-producing industries held steady in June, as the number of jobs in mining, construction, and manufacturing hardly changed at all. The factor workweek remained at a very high level, however—41 hours. Factory overtime, at 3.7 hours in June, was still quite high by historical standards.

Each quarter, Mr. Chairman, we present data on discouraged workers—those who report that they would like to work but have not searched for work because they believe that no jobs are available. At 1 million in the second quarter of 1987, the number of discouraged workers declined by about 130,000 from the first quarter. This was the lowest level since the onset of the 1981-82 recession. Discouragement had reached a high of 1.8 million workers at the end of 1982.

The combined effect of discouragement together with unemployment and involuntary part-time work can be seen in the quarterly BLS U-7 series that appears in table A-5 in our news release. All three measures dropped in the second quarter, and U-7 declined from 10 percent in the January to March period to 9.3 percent in the April to June period. Over the same time, the civilian jobless rate fell from 6.7 to 6.2 percent.

In summary, the data released this morning show a drop in joblessness in June but very little change in employment. Factory employment stayed at the May level, and the pace of job growth in services slowed.

I'd like very briefly to comment on our annual news release on international comparisons of manufacturing productivity and labor cost trends, which was issued since I last appeared here. The figures indicate that the competitive situation for U.S. manufacturers—vis-a-vis Japan and industrial Europe—improved greatly in 1986.

U.S. manufacturing labor productivity, real output per hour, rose 3.5 percent from 1985 to 1986. While the increase was less than in 1985, it was well above the average of the last 13 years. It also exceeded the gains recorded by Canada, Japan, and the seven European countries for which we have comparative 1986 measures. Factory productivity rose about 3 percent in Japan and the United Kingdom, about 1 to 2 percent in France, Germany, Italy, and Sweden, and fell in Canada, Denmark, and Norway.

In addition, manufacturing unit labor costs, which reflect changes in both labor productivity and hourly compensation costs, fell about one-half of 1 percent in the United States, while rising about 1 percent in Japan and by 2.5 to 10 percent in the other countries. Measured on a U.S. dollar basis, to take account of the strong appreciations, of the yen and European currencies, unit labor costs rose over 40 percent in Japan and by about 20 to 40 percent in the European countries.

The Japanese and European currencies continued to appreciate against the U.S. dollar in the first half of this year and U.S. manufacturing unit labor costs fell at an annual rate of about 3 percent in the first quarter. This should help to improve our competitive situation still further.

Mr. Chairman, we will be very happy to try to answer any questions.

Senator SARBANES. Thank you very much, Commissioner.

Unemployment rates of all civilian workers by alternative seasonal adjustment methods

SOURCE: U.S. DEPARTMENT OF LABOR Bureau of Labor Statistics July 1987

~

4

(1) Unadjusted rate. Unemployment rate for all civilian workers, not seasonally adjusted.

(2) Official procedure (X-11 ARIMA method). The published seasonally adjusted rate for all civilian workers. Each of the 3 cajor civilian labor force components--agricultural employment, nonagricultural apployment and unemployment-for 4 age-sex groups--males and females, ages 16-19 and 20 years and over--are seasonally adjusted independently using data from January 1975 forward. The data series for each of these 12 components are extended by a year at each end of the original series using ARIMA (Auto-Regressive, Integrated, Noving Average) models chosen specifically for each series. Each extended series is then seasonally adjusted with the X-11 portion of the X-11 ARIMA program. The 4 teenage unemployment and nonagricultural employment are adjusted with the additive adjustement model, while the other components are adjusted with the multiplicative model. The unemployment fat total as a percent of the civilian labor force total derived by summing all 12 seasonally adjusted factors for Jaluy-December are computed in the middle of the year after the June data become available. Each set of 6-month factors are published in advance, in the January and July issues.

(3) <u>Concurrent (as first computed, X-11 ARIMA method)</u>. The official procedure for computation of the rate for all civilian workers using the 12 components is followed except that extrapolated factors are not used at all. Each component is seasonally adjusted with the X-11 ARIMA program each month as the most recent data become available. Rates for each month of the current year are shown as first computed; they are revised only once each year, at the end of the year when data for the full year become available. For example, the rate for January 1985 would be based, during 1985, on the adjustment of data from the period January 1985.

(4) <u>Concurrent (revised, X-11 ARIMA method)</u>. The procedure used is identical to (3) above, and the rate for the current month (the last month displayed) will always be the same in the two columns. However, all previous months are subject to revision each month based on the seasonal adjustment of all the components with data through the current month.

(5) <u>Stable (X-11 ARIMA method</u>). Each of the 12 civilian labor force components is extended using ARIMA models as in the official procedure and then run through the X-11 part of the program using the stable option. This option assumes that aeasonal patterns are basically constant from year-to-year and computes final seasonal factors as unweighted averages of all the seasonal-irregular components for each month across the entire span of the period adjusted. As in the official procedure, factors are extrapolated in 6-month intervals and the series are revised at the end of each year. The procedure for computation of the rate from the seasonally adjusted components is also identical to the official procedure.

(6) Total (X-11 ARIMA method). This is one alternative aggregation procedure, in which total unemployment and civilian labor force levels are extended with ARIMA models and directly adjusted with multiplicative adjustment models in the X-11 part of the program. The rate is computed by taking seasonally adjusted total unemployment as a percent of seasonally adjusted total civilian labor force. Factors are extrapolated in o-month intervals and the series revised at the end of each year.

(7) Residual (X-11 ARIMA method). This is another alternative aggregation method, in which total civilian employment and civilian labor force levels are extended using ARIMA models and then directly adjusted with multiplicative adjustment models. The seasonally adjusted is derived by subtracting seasonally adjusted employment from seasonally adjusted labor force. The rate is then computed by taking the derived unemployment level as a percent of the labor force level. Factors are extrapolated in 6-month intervals and the series revised at the end of each year.

(8) <u>X-11 method (official method before 1980)</u>. The method for computation of the official procedure is used except that the series are not extended with ARIMA models and the factors are projected in 12-month intervals. The standard X-11 program is used to perform the seasonal adjustment.

<u>Methods of Adjustment</u>: The X-11 ARIMA method was developed at Statistics Canada by the Seasonal Adjustment and Times Series Staff under the direction of Estela Bee Dagum. The method is described in The X-11 ARIMA Seasonal Adjustment Method, by Estela Bee Dagum, Statistics Canada Catalogue No. 12-564E, February 1980.

The standard X-11 method is described in X-11 Variant of the Census Method II Seasonal Adjustment Program, by Julius Shiskin, Allan Young and John Musgrave (Technical Paper No. 15, Bureau of the Census, 1967).

TRANSMISSION OF MATERIAL IN THIS RELEASE IS EMBARGOED UNTIL 8:30 A.M. (EDT), THURSDAY, JULY 2. 1987

Washington, D.C. 20212

THE EMPLOYMENT SITUATION: JUNE 1987

Employment was little changed in June and unemployment declined, the Bureau of Labor Statistics of the U.S. Department of Labor reported today. The overall jobless rate was 6.0 percent and the civilian rate was 6.1 percent, each two-tenths of a point below May levels.

Nonagricultural payroll employment -- as measured by the survey of business establishments--and total civilian employment--as measured by the survey of households--were about unchanged in June, after seasonal adjustment. Both surveys showed increases of roughly 2-1/2 million over the past year.

Unemployment (Household Survey Data)

The number of unemployed declined by 285,000 to 7.3 million, and the civilian unemployment rate fell two-tenths of a percentage point to 6.1 percent. The June jobless rate represented an improvement of six-tenths of a point in the first half of 1987 and was at its lowest point since December 1979.

Fewer young people than normal had entered the labor force as of the June survey week, which was unusually early this year. As a consequence, after geasonal adjustment, declines occurred for both youth employment and unemployment. Teenagers accounted for more than two-thirds of the decline in the number of jobseekers. Their jobless rate fell almost 2 percentage points to 15.9 percent, and that for black teenagers was down nearly 6 percentage points to 33.3 percent. There was also a decline in unemployment among adult women, with their rate edging down two-tenths of a point to 5.2 percent. The rate for adult men was unchanged at 5.5 percent.

Unemployment rates for whites (5.2 percent) and Hispanics (8.5 percent) were little changed, but the rate for blacks (12.7 percent) was down about a percentage point. (See tables A-2 and A-3.)

Civilian Employment and the Labor Force (Household Survey Data)

Civilian employment, following an unusually large rise in the previous month, changed little in June, after seasonal adjustment. Much of the lackluster June employment performance was attributable to agriculture, which picked up fewer than half of its normal May-to-June employment rise, thus falling by 155,000 on a seasonally adjusted basis. Despite June's weakness, the employment total of 112.3 million wis 2.5 million higher than a year earlier. (See table A-1.)

7

After rising in May, the rate of labor force participation returned to the April level of 65.4 percent. Participation rates for adult men and women were each down two-tenths of a percentage point to 78.0 and 56.1 percent, respectively. The rate for teens fell more than 2 points to 53.0 percent. While the labor force declined in June, it has grown by 1.5 million over the past 12 months to a level of 121.2 million.

Discouraged Workers (Household Survey Data)

In the second quarter of 1987, there were about 1.0 million discouraged workers--persons who wanted to work but had not looked for jobs because they believed they could not find any. This was a slight improvement from the 1.1 million in the previous quarter. Two-thirds of these persons cited problems with the job market as their reason for not searching for work, while the rest cited personal factors (such as age or educational deficiencies). Blacks accounted for a disproportionately large share of the discouraged workers--29 percent. (See table A-14.)

Industry Payroll Employment (Establishment Survey Data)

Total nonagricultural payroll employment rose about in line with what is expected for this time of year and, after seasonal adjustment, was about unchanged at 101.8 million in June. This was the second month in a row that there was little job growth in business establishments. The job count was 2.5 million above its year-earlier level, however, with nearly all the growth in the service-producing sector. (See table B-1.)

In June, job growth slowed in the service-producing sector. A small gain occurred in the services industry, most of it in health services. In the goods-producing sector, construction employment remained near its May level after seasonal adjustment. Job gains in the industry this spring have barely kept up with seasonally-expected growth. Employment in mining and its oil and gas extraction component was unchanged from May but has shown small gains thus far in 1987, following large declines in 1986. Manufacturing employment was unchanged over the month, after also posting small gains earlier in the year.

Weekly Hours (Establishment Survey Data)

The average workweek of production or nonsupervisory workers on private nonagricultural payrolls edged down 0.1 hour to 34.8 hours, seasonally adjusted. The manufacturing workweek was unchanged at 41.0 hours, and factory overtime inched down by 0.1 hour to 3.7. Both figures have recently been very high by historical standards. (See table B-2.)

The index of aggregate weekly hours of production or nonsupervisory workers on private nonagricultural payrolls was virtually unchanged at 120.1 (1977=100) in June, seasonally adjusted. This was nearly 3 percent higher than the June 1986 index. (See table B-5.) Hourly and Weekly Earnings (Establishment Survey Data)

On a seasonally adjusted basis, average hourly earnings and averag weekly earnings were about unchanged in June. Prior to seasona adjustment, hourly earnings remained at \$8.93, while weekly earnings wer up \$1.79 to \$312.55. (See table B-3.)

The Hourly Earnings Index (Establishment Survey Data)

The Hourly Earnings Index (HEI) was 173.1 (1977=100) in June seasonally adjusted, an increase of 0.2 percent from May. For the 12 month ended in June, the increase was 2.3 percent. The HEI excludes the effect of two types of changes unrelated to underlying wage rat movements--fluctuations in manufacturing overtime and interindustr employment shifts. In dollars of constant purchasing power, the HE decreased 1.4 percent during the 12-month period ended in May. (See tabl B-4.)

The Employment Situation for July 1987 will be released on Friday, August 7, at 8:30 A.M. (EDT).

Explanatory Note

This news release presents statistics from two major surveys, the Current Population Survey (household survey) and the Current Employment Statistics Survey (establishment survey). The household survey provides the information on the labor force, total employment, and unemployment that appears in the A tables, marked HOUSEHOLD DATA. It is a sample survey of about 59,500 households that is conducted by the Bureau of the Census with most of the findings analyzed and published by the Bureau of Labor Statistics (BLS).

The establishment survey provides the information on the employment, hours, and earnings of workers on nonagricultural payrolls that appears in the B tables, marked ESTABLISHMENT DATA. This information is collected from payroll records by BLS in cooperation with State agencies. The sample includes over 290.000 establishments employing over 38 million people.

For both surveys, the data for a given month are actually collected for and relate to a particular week. In the household survey, unless otherwise indicated, it is the calendar week that contains the 12th day of the month, which is called the survey week. In the establishment survey, the reference week is the pay period including the 12th, which may or may not correspond directly to the calendar week.

The data in this release are affected by a number of technical factors, including definitions, survey differences, seasonal adjustments, and the inevitable variance in results between a survey of a sample and a census of the entire population. Each of these factors is explained below.

Coverage, definitions, and differences between surveys

The sample households in the household survey are selected so as to reflect the entire civilian noninstitutional population 16 years of age and older. Each person in a household is classified as employed, unemployed, or not in the labor force. Those who hold more than one job are classified according to the job at which they worked the most hours.

People are classified as *employed* if they did any work at all as paid civilians: worked in their own business or profession or on their own farm; or worked 15 hours or more in an enterprise operated by a member of their family, whether they were paid or not. People are also counted as employed if they were on unpaid leave because of illness, bad weather, disputes between labor and management, or personal reasons. Members of the Armed Forces stationed in the United States are also included in the employed total.

People are classified as unemployed, regardless of their eligibility for unemployment benefits or public assistance, if they meet all of the following criteria: They had no employment during the survey week; they were available for work at that time; and they made specific efforts to find employment sometime during the prior 4 weeks. Persons laid off from their former jobs and awaiting recall and those expecting to report to a job within 30 days need not be looking for work to be counted as unemployed.

The labor force equals the sum of the number employed and the number unemployed. The unemployment rate is the percentage of unemployed people in the labor force (civilian plus the resident Armed Forces). Table A-5 presents a special grouping of seven measures of unemployment based on varying definitions of unemployment and the labor force. The definitions are provided in the table. The most restrictive definition yields U-1 and the most comprehensive yields U-7. The overall unemployment rate is U-3a, while U-5b represents the same measure with a divilian labor force base.

Unlike the household survey, the establishment survey only counts wage and salary employees whose names appear on the payroll records of nonagricultural firms. As a result, there are many differences between the two surveys, among which are the following:

— The household survey, although based on a smaller sample, reflects a larger segment of the population; the establishment survey excludes agriculture, the self-employed, unpaud family workers, private household workers, and members of the resident Armed Forces;

- The household survey includes people on unpaid leave among the employed, the establishment survey does not;

- The household survey is limited to those 16 years of age and older; the establishment survey is not limited by age;

— The household survey has no duplication of individuals, because each individual is counted only once; in the establishment survey, employees working at more than one job or otherwise appearing on more than one payroll would be counted separately for each appearance.

Other differences between the two surveys are described in "Comparing Employment Estimates from Household and Payroll Surveys," which may be obtained from the BLS upon request.

Seasonal adjustment

Over the course of a year, the size of the Nation's labor force and the levels of employment and unemployment undergo sharp fluctuations due to such seasonal events as changes in weather, reduced or expanded production, harvests, major holidays, and the opening and closing of schools. For example, the labor force increases by a large number each June, when schools close and many young people enter the job market. The effect of such seasonal variation can be very large; over the course of a year, for example, seasonality may account for as much as 95 percent of the month-to-month changes in unemployment.

60_#CH 40

Because these seasonal events follow a more or less regular pattern each year, their influence on statistical trends can be eliminated by adjusting the statistics from month to month. These adjustments make nonseasonal developments, such as declines in economic activity or increases in the participation of women in the labor force, easier to spot. To return to the school's-out example, the large number of people entering the labor force each June is likely to obscure any other changes that have taken place since May, making it difficult to determine if the level of economic activity has risen or declined. However, because the effect of students finishing school in previous years is known, the statistics for the current year can he adjusted to allow for a comparable change. Insofar as the seasonal adjustment is made correctly, the adjusted figure provides a more useful tool with which to analyze changes in economic activity.

Measures of labor force, employment, and unemployment contain components such as age and sex. Statistics for all employees, production workers, average weekly hours, and average hourly earnings include components based on the employer's industry. All these statistics can be seasonally adjusted either by adjusting the total or by adjusting each of the components and combining them. The second procedure usually yields more accurate information and is therefore followed by BLS. For example, the seasonally adjusted figure for the labor force is the sum of eight seasonally adjusted civilian employment components, plus the resident Armed Forces total (not adjusted for seasonality), and four seasonally adjusted unemployment components; the total for unemployment is the sum of the four unemployment components; and the overall unemployment rate is derived by dividing the resulting estimate of total unemployment by the estimate of the labor force.

The numerical factors used to make the seasonal adjustments are recalculated regularly. For the household survey, the factors are calculated for the January-June period and again for the July-December period. The January revision is applied to data that have been published over the previous S years. For the establishment survey, updated factors for seasonal adjustment are calculated only once a year, along with the introduction of new benchmarks which are discussed at the end of the next section.

Sampling variability

Statistics based on the household and establishment surveys are subject to sampling error, that is, the estimate of the number of people employed and the other estimates drawn from these surveys probably differ from the figures that would be obtained from a complete census, even if the same questionnaires and procedures were used. In the household survey, the amount of the differences can be expressed in terms of standard errors. The numerical value of a standard error depends upon the size of the sample, the results of the survey, and other factors. However, the numerical value is always such that the chances are approximately 68 out of 100 that an estimate based on the sample will differ by no more than the standard error from the results of a complete census. The chances are approximately 90 out of 100 that an estimate based on the sample wil differ by no more than 1.6 times the standard error from the results of a complete census. At approximately the 90-percent level of confidence—the confidence limits used by 8LS in its analyses—the error for the monthly change in total employment is on the order of plus or minus 328,000; for total unemployment it is 220,000; and, for the overall unemployment rate, it is 0.19 percentage point. These figures do not mean that the sample results are off by these magnitudes but, rather, that the chances are approximately 90 out of 100 that the "true" level or rate would not be expected to differ from the estimates by more than these amounts.

Sampling errors for monthly surveys are reduced when the data are cumulated for several months, such as quarterly or annually. Also, as a general rule, the smaller the estimate, the larger the sampling error. Therefore, relatively speaking, the estimate of the size of the labor force is subject to less error than is the estimate of the number unemployed. And, among the unemployed, the sampling error for the jobless rate of adult men. for example, is much smaller than is the error for the jobless rate of teenagers. Specifically, the error on monthly change in the jobless rate for men is .26 percentage point; for teenagers, it is 1.25 percentage points.

In the establishment survey, estimates for the 2 most current months are based on incomplete returns; for this reason, these estimates are labeled preliminary in the tables. When all the returns in the sample have been received, the estimates are revised. In other words, data for the month of September are published in preliminary form in October and November and in final form in December. To remove errors that build up over time, a comprehensive count of the employed is conducted each year. The results of this survey are used to establish new benchmarks—comprehensive counts of employment—against which month-to-month changes can be measured. The new benchmarks also incorporate changes in the classification of industries and allow for the formation of new establishments.

Additional statistics and other information

In order to provide a broad view of the Nation's employment situation, BLS regularly publishes a wide variety of data in this news release. More comprehensive statistics are contained in *Employment and Earnings*, published each month by BLS. It is available for \$8.50 per issue or \$22.00 per year from the U.S. Government Printing Office, Washington, D.C., 20204. A check or money order made out to the Superintendent of Documents must accompany all orders.

Employment and Earnings also provides approximations of the standard errors for the household survey data published in this release. For unemployment and other labor force categories, the standard errors appear in tables B through J of its "Explanatory Notes." Measures of the reliability of the data drawn from the establishment survey and the actual amounts of revision due to benchmark adjustments are provided in tables M, O, P, and Q of that publication.

Date relate to production workers in mining and manufacturing; to construction workers in construction; and to nonsupervisory workers in transportation and public utilities; wholeset and reall vizor, finance, instruction, and create state; and services. These groups account for approximately four-fitting of the total employees on private nonsproclutural pervols. ¹ This series is not published seasonalty adjusted since the seasonal component is small feature to the tend-cycle and/or irregular components and consequently cannot be separated with sufficient precision. p. preliminary.

Senator SARBANES. Let me pursue the last part of your statement first, on productivity comparisons.

In looking at those figures, and given the fact on a comparative basis we are doing better internationally on the productivity front, to what extent do we have to try to factor in where the respective economies are in terms of the economic cycle?

Mrs. NORWOOD. I think that's terribly important. If we are to regain not only our competitiveness but equally importantly if we are to reduce the deficit in international trade, it's going to have to be because of purchases by other countries. That means that their economies are going to have to keep moving upward.

There's been a great deal of discussion about how to achieve that. On the cost side, I think these data suggest that because of improved productivity in the United States in manufacturing and shifts in the exchange rates, we are doing much better.

Senator SARBANES. Is the poor productivity performance in these other countries due in part becaue of what's happening to them in terms of cyclical movement of their economy?

Mrs. NORWOOD. There may be some of that. I think it is partly due to differences in our labor markets. The data we released today show that there has been a continuation of increasing efficiency within manufacturing. We are continuing to produce output and we are not adding labor force.

Senator SARBANES. Let me ask about that because I have read some reports that there's been a movement—I don't know how extensive—by manufacturing firms to lease labor from outside firms rather than to hire the labor directly. I gather if that happens, employment is not listed as manufacturing but is listed instead under business services. Is that correct?

Mrs. Norwood. That's correct.

Senator SARBANES. In which case, of course, that would understate the number of people working in manufacturing and I assume would overstate productivity.

Mrs. Norwood. Yes, that could happen.

Senator SARBANES. Because when you calculate the productivity, you don't encompass within it the business services category, do you?

Mrs. NORWOOD. Well, what you would encompass is the cost of those services. If the manufacturing establishments are paying the costs of those workers, that goes into the overall calculations.

Senator SARBANES. Okay. So it would affect the employment.

Mrs. NORWOOD. Mr. Mark tells me that output is measured on a value added basis and so it's adjusted for that.

We are not sure, Mr. Chairman, exactly how much contracting out is occurring. There's always been a good deal of contracting out. We did a very quick small survey recently to try to see whether there was very much of a change, particularly in some industries which had a decline in employment, some of the manufacturing industries. And we found that many of them were contracting out and that some had increased their contracting out.

The data were not as conclusive as, I must say, I had anticipated they would be. We are planning a survey of the temporary help industry as one of our occupational wage programs this coming year and I anticipate that we will learn a lot more once we have those data available.

Senator SARBANES. In your statement you say that the labor force for the 16- to 24-year group has risen considerably less than last year, and you say it's risen this year 2.6 million. How much was it last year?

Mrs. Norwood. About 3.5 million.

Senator SARBANES. And do you have an explanation for the difference?

Mrs. Norwood. There may be several explanations. One that we have to look at—and I'm not sure how important it is—is that the survey week came somewhat earlier than is usual. The 12th of the month fell on a Friday. The result is that we may have missed some of the people who would be coming into the labor force in the following week.

About two-thirds of the drop in the unemployment rate in the month of June came from the teenage component.

Senator SARBANES. So two-thirds of it is attributable to the factor we're talking about now, that is essentially the size of that labor force?

Mrs. Norwood. Yes.

Senator SARBANES. The improvement in the unemployment rate is due not to more jobs but fewer people in the job market, is that correct, for this month?

Mrs. Norwood. Yes. That's what the arithmetic shows quite clearly. The change in employment is not statistically significant in either of the surveys. There has been quite a lot of growth over the last 6 months, but there has clearly it seems to me been something of a slowdown in the last 2 months.

Senator SARBANES. The jobless rate for adult women is less than the jobless rate for adult men?

Mrs. Norwood. Yes.

Senator SARBANES. That's a historical reversal, is it not?

Mrs. Norwood. Yes, it is. What has happened in the past is that the unemployment rate for women has generally been higher than the unemployment rate for men in good times as well as bad. During a recessionary period, as more men are laid off, the gap between the two has narrowed.

During the most recent recession, that situation reversed and has really stayed reversed because of the changes that are going on in manufacturing where only about 40 percent of the employment lost during the recession that has been recovered and because manufacturing has a very high proportion of males in its work force.

Senator SARBANES. In other words, as we have moved out of the recession, 60 percent of the jobs in manufacturing have not been recovered, is that correct?

Mrs. Norwood. That's correct.

Senator SARBANES. And, of course, that then impacts disproportionately on males. What percentage of manufacturing jobs are held by males, do you know?

Mrs. Norwood. Roughly two-thirds of all manufacturing jobs are held by men.

Senator SARBANES. Is there any other factor or factors explaining this reversal of the historical trend in terms of unemployment among males and unemployment among women?

Mrs. NORWOOD. Yes, I think so. One important factor is the change in the educational attainment of women in this country. Many women now go on to college and have the education that our projections show is going to be needed in terms of the kinds of jobs that we are creating.

So I think we have a better educated female work force than we did 20 years ago.

Senator SARBANES. Well, thank you very much.

Congressman McMillan.

Representative McMILLAN. Thank you, Mr. Chairman.

I would also like to add my congratulations to you, Mrs. Norwood, on your reappointment as Commissioner. I am new on the committee, but I have been impressed with your objectivity and I want to thank you for that and wish you well.

Mrs. Norwood. Thank you very much.

Representative McMILLAN. Now I also have, Mr. Chairman, an opening statement that I would like to submit for the record.

Senator SARBANES. The opening statement will be included in full in the record.

[The written opening statement of Representative McMillan follows:]

WRITTEN OPENING STATEMENT OF REPRESENTATIVE MCMILLAN

IT GIVES DE GREAT PLASURE TO WELCOME COMPLESIONER NORWOOD HERE THIS MORNING. L'DITKE TO TAKE HES OPPORTUNITY TO CONGRATHEATE DR. NORWOOD FOR SENATE CONFIRMATION OF HER NOMINATION FOR ANOTHER FERM AS BES COMPLESIONER. AMONG MUBBERS OF BOTH HOUSES OF CONGRESS DR. NORWOOD AND BES ENJOY A STERING REPUTATION FOR HELE STANDARDS AND NONPARTISAN OPERATION. WE LOOK FORWARD TO WORKING WITH YOU AND THE BUREAU IN THE FUTURE.

ONCE AGAIN COMMISSIONER NORWOOD BRINGS VERY GOOD NEWS. THE CIVELIAN UNEMPLOYMENT RATE DECLINED TWO TENTHS OF A POINT IN JUNE TO A LEVEL OF G.1 PERCENT. THIS IS THE LOWEST UNEMPLOYMENT RATE SINCE THE LND OF 1972.

29

THE EMPLOYMENT-POPULATION RATIO, AN IMPORTANT MEASURE OF OUR ECONOMY'S ABILITY TO CREATE ENOUGH JOBS, ALSO SIGNALS ECONOMIC STRENGTH. THOUGH DOWN SLIGHTLY FROM THE RECORD HIGH OF LAST MONTH, THE 61.4 PERCENT JUNE C-P RATIO IS EXTREMELY HIGH BY HISTORICAL STANDARDS. ASTDE FROM LAST MONTH, ITS LEVEL IS THE HIGHEST EVER RECORDED.

THE ECONOMIC PROGRESS MADE DURING THIS EXPANSION IS IMPRESSIVE. DURING THE 55 MONTHS OF THIS UPSWING OVER 13 MILLION JOBS HAVE BEEN CREATED, EVEN AS THE INFLATION RATE DECLINED FROM THE DOUBLE DIGIT LEVELS OF THE LAFE 1970'S. THOUGH PROBLEMS REMAIN, THE EVIDENCE CERTAINLY DOES NOT SUPPORT THOSE WHO CONSTANTLY VOICE PESSIMISM ABOUT THE DIRECTION OF THE ECONOMY. RECENT EMPLOYMENT DATA SHOW THAT THE ECONOMY CONTINUES TO IMRPOVE, AND THE RECENT INCREASES IN THE LEADING INDICATORS MEAN THIS EXPANSION WILL PROBABLY CONTINUE FOR THE FORESEEABLE FUTURE.

ANOTHER ENCOURAGING DEVELOPMENT IS THE GREAT IMPROVEMENT IN U.S. INTERNATIONAL COMPETITIVENESS IN 1986. ACCORDING TO BLS, U.S. MANUFACTURING PRODUCTIVITY INCREASED 3.5 PERCENT BETWEEN 1985 AND 1986, EXCEEDING PRODUCTIVITY GROWTH IN MOST OTHER ADVANCED INDUSTRIAL NATIONS. MOREOVER, UNIT LABOR COSTS IN MANUFACTURING ACTUALLY DECLINED IN THE U.S., WHILE INCREASING IN MOST OF EUROPE AND JAPAN. THESE POSITIVE TRENDS SHOULD LEAD TO IMPROVED U.S. EXPORT PERFORMANCE AND FURTHER DECLINE IN THE TRADE DEFICIT. Representative McMILLAN. I think some of the underlying trends that we've been talking about are interesting. Your comments with respect to educational levels of women versus men that might be entering the work force is somewhat confirmed by a few figures that I have in my head. For example, I think the entering class at the University of North Carolina at Chapel Hill last year was approximately 63 percent women, and I think that's occurred in some other universities with which I'm familiar.

That might in itself be an interesting study because we are not just talking about what exists today but what may exist in the future and the employment ratio that you referred to earlier of women versus men, in a period in which the economy is undergoing shifts to higher technology in which a different set of educational skills and abilities may be applicable, you suggest that that in fact may favor women in the work force as opposed to men?

Mrs. Norwoon. I think the point I was making was that the difference in the 1980's from that in the 1950's, for example, and the 1960's, when we had a much higher unemployment rate for women compared to men, may be in part attributable to the fact that during that period many, many more women have gone on to get better educations. And it's quite clear that both men and women in the future are going to need the kind of educational background that is required for jobs that require special technology and special kinds of skills.

That has nothing to say, I might add, with the quality of education that we are providing. That's another question and a very important one I believe.

Representative McMILLAN. So the short-term figures that we are looking at in this period really are a continuation of a trend that has existed for some period of time?

Mrs. Norwood. Yes.

Representative McMILLAN. Could you trace back historically when that began to reflect itself statistically and add any comments to that that you perceive for the future?

Mrs. NORWOOD. We could provide a statement for the record on that. We'll go back and look at women and men and their educational attainment. We do have data of that kind in the labor force over the last several decades. We'd be glad to do that and send you that information.

[The following information was subsequently supplied for the record:]

U.S. Department of Labor

Commissioner for Bureau of Labor Statistics Washington, D.C. 20212

JUL 10 1987

Honorable J. Alex McMillan House of Representatives Washington, D.C. 20515

Dear Congressman McMillan:

I am responding to two questions you raised during my July 3 testimony before the Joint Economic Committee. They related to the educational attainment of women in the labor force and to the youth share of discouraged workers.

As the tabulation below shows, the educational level of women in the labor force has, indeed, improved considerably (even more than for men) since the end of the 1970 decade. All other things being equal, that trend should have had some downward effect on the unemployment rate for women.

Percent distribution of the labor force by educational attainment for men and women age 25-64, 1979 and 1986

Educational	M	en	Women		
attainment	1979	1986	1979	1986	
Total	00.0	100.0	100.0	100.0	
Less than 4 years of high school.	23.2	17.2	20.1	13.2	
High school, 4 years	35.7	37.0	45.2	44.3	
1-3 years of college	17.4	18.9	17.1	20.3	
4 or more years of college	23.7	26.9	17.1	22.2	

The following tabulation provides the age distribution of discouraged workers (the 1986 annual average was chosen rather than the slightly more current, but not seasonally adjusted, quarterly data).

Honorable J. Alex McMillan--2

JUL 10 1987

Percent distribution of discouraged workers by age and sex, 1986 annual averages

Age	<u>Total</u>	Men	Women
Total	100.0	38.9	61.1
16 to 19 years	10.7	6.1	4.6
20 to 24 years	14.3	5.8	8.4
25 to 54 years	52.6	17.1	35.6
55 years and over	22.5	10.0	12.6

As shown, youths 16 to 24--who make up about 19 percent of the noninstitutional population 16 years of age and over-accounted for 25 percent of the discouraged workers in 1986.

I hope this information will have answered your questions. Please let me know if we can be of further assistance.

Sincerely yours,

Jaset L howwood

JANET L. NORWOOD Commissioner

Representative McMILLAN. Well, I think that would be important in informing the Congress about some of its responsibilities.

Also, I would be interested in any further comments you may have with respect to trends in teenage unemployment or employment and the size of the work force and particularly as it may impact minorities because that's been I think a concern of all of us. Could you put the figures for June—and I realize we may have some statistical problem with respect to comparative timeframe, but put it in a little bit of historical perspective in terms of what this may say or not say about the longer term trends?

Mrs. Norwood. In June, there was a drop in the unemployment rate for black Americans. The labor force situation for blacks has been changing. The unemployment rate for black teenagers was 33.3 percent, still extraordinarily high, but it is well below the 40 to 50 percent rate that we have had earlier in the 1980's.

Representative McMILLAN. Excuse me. Would you say that's seasonal or do you see in that some reversal of what we have generally considered to be adverse trend?

Mrs. Norwood. Over the last several years there has been a declining unemployment rate for black teenagers. However, I'm not certain how much of the June decline—from 39 percent to 33.3 percent—will remain with us after another couple of months. We need to have a little bit more time to see that.

In general, however, the black population as a whole, including black teenagers, have done a little bit better during the recovery than they had previously. But I think it should be understood that during the 1980 and the 1981–82 recessions their labor force status deteriorated quite a bit.

There are fewer teenagers generally in the population. The birth rate of the black population declined less than the birth rate of the white population.

Representative McMILLAN. When you say fewer, are you speaking in relative terms or absolute terms?

Mrs. Norwood. Well, for teenagers as a whole, we have seen some reduction absolutely in the work force of teenagers. Their labor force declined by about 200,000 over the last year.

I think what we are anticipating is that as we move through the rest of this century we will be seeing a work force that is going to be growing older merely because there will be fewer teenagers entering that work force. We anticipate that it will be about 1992 or so before that situation turns around. That should mean less upward pressure on the unemployment rate since teenagers always have much higher unemployment rates than others.

On the other hand, a much larger proportion of the entire work force and of the teenage work force in the future will be made up of minorities than in the past, and that could be a very serious problem for us unless we are able to move those people into more rewarding jobs.

Representative McMILLAN. One other question. You talked a little bit today about the statistics that represent discouraged workers. What are the criteria by which a person falls into that classification?

Mrs. Norwood. A discouraged worker is one who wants a job but does not meet the definition for unemployment. To be classified as unemployed requires that a person must not have worked during the survey week, be available for work, and have searched for work during the preceding 4 weeks. A discouraged worker meets the first two criteria, but does not meet the last, and says that he has not searched for work because essentially he or she believes that it would be of no value.

We do not include discouraged workers in the official unemployment rate because they have not made any recent attempt to look for a job. Discouragement is really a state of mind and our labor force definitions refer to specific activities that can be measured.

I did refer in my statement to one of the array of unemployment rates U-7 that we publish which does include discouraged workers. The data were quite encouraging in that we have seen a continued decline in the number of discouraged workers, but a million is still a lot of people.

Representative McMILLAN. Do we develop that statistic and apply it to teenage workers?

Mrs. Norwood. Yes. All people 16 years and over are included in those data. Discouraged workers are disproportionately women and minorities.

Representative McMILLAN. Well, Congress is going to be considering legislation with respect to the minimum wage, and one of the issues I think has to do with entry level jobs and that tends to focus on the teenager. And that discouragement index it seems to me becomes more sensitive under these circumstances. And I would hope that maybe we could get a little additional information on that to perhaps inform the Congress in its judgment it's going to try to make on that issue in the coming weeks.

Mrs. NORWOOD. Yes, certainly we can do that. We have already provided a great deal of information to congressional staffs on both sides of the aisle on the demographic characteristics of people involved in minimum wage and low wage jobs. We would be glad to do whatever else we can.

Representative McMILLAN. Thank you, Mrs. Norwood.

Thank you, Mr. Chairman.

Senator SARBANES. Commissioner, is the survey week the same week every month?

Mrs. Norwood. It's the calendar week containing the 12th of the month. So, depending on where the 12th falls, the week may be earlier or later in the month.

Senator SARBANES. Senator Melcher.

Senator MELCHER. Mrs. Norwood, you wouldn't mind answering a couple questions on a different subject, would you?

Mrs. Norwood. Not at all.

Senator MELCHER. You testified before the Aging Committee a few days ago that if you were asked or required by Congress to prepare a different consumer price index for older Americans that it would cause you some problems and would take some time.

Were those problems other than time connected with what were older Americans, a definition of older Americans?

Mrs. Norwood. I believe, Senator, that I did emphasize to you the need for us, if we are to create a new statistical measure, to be able very specifically to define the group whose experience we want to reflect. And I pointed out to you I think basically two things.

First, who are the older people? That is always difficult to define depending on your own age I suppose. But if we take those 65 to 74, their expenditure experience is similar to that of the general population. The biggest expenditure changes occur after age 75. Another definitional point that we discussed, as I recall, was whether such an index should be confined to the retired.

The other point that I made was that in order to produce a truly accurate CPI for older Americans, however defined, we would need to do a great deal that we have not now done and expand some of our samples and that that would take some time and some money, but that there were some shortrun kinds of things that could be done and if coupled with some expansion of survey work and analysis I think they could be quite useful.

Senator MELCHER. Did you tell the same thing to the conferees that were meeting on the appropriations bill that had that requirement in it?

Mrs. Norwood. I have had no contact with the conferences on the appropriations bill, Senator.

Senator MELCHER. What has the liaison for the Department of Labor told the conferees?

Mrs. Norwood. I do not know. I would guess that they probably have told the conferees——

Senator MELCHER. The same thing you just said?

Mrs. NORWOOD. No. That it is the administration's position not to add things that might cost money, that that could be a problem. Senator MELCHER. Precisely.

Mrs. Norwood. That's not necessarily my position.

Senator MELCHER. Then what the conferees may have been told is that if you develop such an index it might lead Congress to say, well, we ought to look at the cost-of-living adjustment to see whether or not the cost-of-living adjustment truly reflects what the difference is in inflation one year to another for retirees who are affected by it, such as on Social Security, railroad retirement, military retirees, and Federal employee retirees? So you surmise that is probably what the administration's position is and what the liaison people from the Bureau of Labor Statistics and the Department of Labor have told the conferees?

Mrs. Norwood. No, sir. The position of the Bureau of Labor Statistics is that we do not know and have no way of knowing whether, if an accurate CPI for older citizens, however defined, were produced, it would show higher or lower price changes. It would be an accurate reflection of the experience of that group, but we have no idea whether it would be higher or lower. That has been very clearly our position.

And I do want to reiterate again that I and my staff have had no contact with the appropriations people. The Congressional Affairs Office of the Department of Labor may have, but they represent the administration's position clearly.

Senator MELCHER. Then they would not be liaison people from the Department of Labor?

Mrs. Norwood. They talk to us, but we have taken no position on this. We don't take policy positions.

Senator MELCHER. Well, I mention that because it's due to the statements made by liaison from the Bureau of Labor Statistics, the report back to me is that they didn't want it and it was dropped.

Mrs. Norwood. Senator, I think there are a few things that seem to get confused in the discussion generally-the broader discussion.

One is, do you need, should you have, what would it cost to produce a CPI for older Americans? That's one issue.

The second issue is, if you had such an index, would Social Security escalation cost the Government more money or less money?

We have no answer to the second question. Obviously, we know what it takes to produce an index and we have some general idea of answers to the first set of questions.

Senator MELCHER. Well, first of all, it would cost money out of the trust fund, whether we want to say that costs the Federal Government money, when we count trust funds as part of the Federal Government's money, I think that's true. But the cost out of the trust fund is the benefit directly, dollar for dollar, to retirees.

I interpreted your answer previously, when you said you suspected that what the conferees may have been told by liaison was that it would cost more money and therefore the administration was opposed to it-

Mrs. Norwood. To produce an index.

Senator MELCHER. Pardon me.

Mrs. Norwood. To produce an index, not necessarily-Senator MELCHER. To produce an index?

Mrs. Norwood. Yes, and that is our position and I was quite clear on that when I testified before the Special Committee on Aging. I have no idea whether such an index would create larger or lower escalation of benefits for Social Security recipients. That's a question we cannot answer. We don't have such an index and we can't answer it.

Senator MELCHER. I think everything that the Department of Labor does does cost money.

Mrs. Norwood. That's true.

Senator MELCHER. I think the annual appropriation proves that fact beyond a doubt. I think what we're talking about here is pennies compared to millions and the issue is whether the millions of Americans are getting the pennies they should out of the trust fund. I very much regret the last minute dropping of that particu-lar portion of the bill because it would have only given you between today and sometime this fall to give us some input as to whether or not we are treating older retirees fairly. Now the time is running and the next time we get a chance to give you that direction will probably be sometime this fall, too late-too late, mind you, to do anything about the cost-of-living adjustment for 1988. Mrs. NORWOOD. You will recall, Senator, that one of the issues

we also discussed was the use of the CPI-U rather than the CPI-W for escalation of Social Security benefits.

Senator MELCHER. Yes, I do recall that, and I recall exactly how that came about. It's simply because that amendment was in here that we're beginning to hear that the CPI-W, the index that is used and does form the basis for the cost-of-living adjustment, doesn't even include any retirees.

Now we're hearing, well, we could change the CPI-U. The only reason we're hearing that now is because the issue was raised was this fair or wasn't this fair? We'd like to get at what the fairness part of this is and that is to look specifically at those items that the retirees must pay—older people must pay in order to live. And they do have a different market basket for the things that they must buy and we've gone over that before and you know it even better than I. So I won't repeat it here, except to say that means health care and public transportation obviously went up 7 to 9 percent last year and those are things that older people have to buy and have to have. They have no choice, and a raise of 1.3 percent in the cost-of-living adjustment simply didn't reflect the inflation they had.

Mrs. NORWOOD. May I just say that it was in 1978 that the Bureau of Labor Statistics raised the issue of whether to use the CPI-U or the CPI-W in escalation of Social Security and other entitlement programs. That's not an issue that is new to us. At least we raised that publicly. It was discussed in the Congress.

The second point is that you're quite right that things like medical care would be weighted much more heavily in an index for the elderly, as would home heating oil, for example, and perhaps food. But such things as college tuition, new cars, and gasoline would be weighted somewhat lower in an index for older Americans.

And its's for those reasons that we really can't say one way or the other exactly what the final distribution would be and where this would come out, whether it would be higher or lower. That's really what I was trying to explain.

Our position—our function at the Bureau of Labor Statistics is to carry out the policy decisions of the Congress and the administration. We don't make policy. We try to be a service agency and if the Congress should decide that it wishes such an index we'll do our best to produce it, provided the resources are there.

One of my concerns about the amendment to the Appropriations Act was that it required us to do something within existing resources, and that would mean that we would have to take it from our employment programs or our other price programs and that would be difficult.

But I'm sure that if you wish to pursue that issue, that there are things that could be done.

Senator MELCHER. Well, I'm sure, too. I only regret the stalling from this bill means that in all likelihood the people who like to stall for one reason or another are going to stall it for another year.

Senator SARBANES. Commissioner, in light of this questioning, I want to be clear for the record on a couple of points.

First of all, as I understand your position, you indicated in this hearing that to produce a special index for older Americans, however we define that, would cost money. In other words, you would have to put some resources into doing it and, therefore, it would cost money. Is that correct?

Mrs. NORWOOD. To produce an accurate index, which included the expenditure experience of those groups that would be using an expenditure survey that was at least as reliable as the Consumer Price Index that is now being used for escalation, to go to the kinds of stores that older people go to, to use the specific items that older people buy, to use the particular prices that they pay since there are special senior citizens prices and so on, would be quite an expensive undertaking.

I did point out at the hearing that the Senator chaired that we could reweight the existing index with data from the existing expenditure survey. Such an index would have a much higher level of error than we would like, and it is our view that the result would be a kind of hybrid index. We could produce this hybrid index with very little cost—but if that were done, it should, in our view, be coupled with some expansion of survey work and some research to get a better handle on these other issues, so that eventually we could produce an index that would be as accurate as the current indexes that we have.

Senator SARBANES. All right. Now on the substantive question of whether a separate special index for older Americans would give them more of a cost-of-living adjustment or less of a cost-of-living adjustment than the current index, which is a general one for everybody——

Senator MELCHER. Would you yield on that point? That's a significant point. The current index does not include any older Americans, any retirees. It's only urban—I don't know whether I should use white collar and blue collar, but in general, it's urban people working for a living, not retirees.

Mrs. Norwood. That's the CPI-W, not the CPI-U.

Senator MELCHER. That does not have any of the retirees in it. Senator SARBANES. Does the CPI-U differ from the CPI-W in any significant way?

Mrs. Norwood. Yes. The CPI-U represents all urban consumers, including the retired. The CPI-W represents less than half of the urban population and represents only those families where more than half of the income comes from a wage earner or clerical worker.

Senator SARBANES. And is there a significant difference in what those two indexes reflect?

Mrs. Norwood. There are some significant differences in the weights, the expenditure weights, the relative importance. There is not a great deal of difference in the movement of those two, but there are occasionally some differences that do come in one or another of the two indexes. They are small.

Senator SARBANES. But in any event, I take it on the question of whether it would show more or less, you just don't know the answer to it?

Mrs. Norwood. That's right.

Senator SARBANES. You wouldn't know that answer unless you actually did the study, is that correct?

Mrs. Norwood. That's correct.

Senator SARBANES. Now third, because I just want to make sure, you or your staff had no contact with the conferees, is that correct?

Mrs. Norwood. We have not. I'm sure the Department of Labor Congressional Affairs staff has and I know that the Bureau of Labor Statistics' position, which I suppose was carried out or communicated by the Department of Labor Congressional Affairs staff, was that the provision which required us to do this within existing resources, I believe was the way it was phrased, was really unacceptable.

Senator SARBANES. If you were provided with the resources and the policy direction to do it, you would do it, of course, would you not?

Mrs. Norwood. Certainly, of course. We'd do it to the best of our ability.

Senator SARBANES. And in fact, would see some argument for doing it, I take it, in order to address the question that keeps coming up as to whether the consumer price adjustment is treating older people fairly.

Mrs. Norwood. I think that one of the witnesses that the Senator had at that hearing expressed it extremely well. That was Arthur Fleming, who said there is a serious credibility question. The indexes might be the same, but if people knew that it reflected older Americans, they would believe it. And now they are unsure whether there may be some differences.

The reason that we don't know whether there would be differences is because when you look at the various components of the CPI and you look at those which have higher weight and which also have higher rates of price increase, you need to balance those by others which would have a lower weight in an index for older Americans and which also may have a higher price change.

So there may be some balancing here and we don't really know exactly how much.

The thing that concerns me is that if we produce some kind of hybird index, and people didn't like the result, whatever that result might be, then they would begin to raise the question of how accurate that index was and compare it to the other indexes.

Senator SARBANES. Well, that index would lack credibility, too. If you're going to do it, you need to produce an index that has credibility and is going to answer the question, do you not?

Mrs. Norwood. Yes, sir. That's our feeling.

Senator SARBANES. But if a judgment were made that we ought to address this credibility question and the resources were provided to the Bureau with which to do it, you would be happy to undertake that task, I take it?

Mrs. NORWOOD. We are a service agency and we are prepared to do whatever the Congress requests that we do.

I would like to make one point, however, and that is that to expand the survey work for consumer expenditures and the stores to which people go, we estimate that we might have to go visit as many as eight households in order to get one that would fit into this group. That's very expensive.

One way to shortcut that, both in time and in cost, would be if we could sample the names and addresses of the Social Security files. We are not able to do that. But that would be a very good shortcut, an efficiency approach, to getting at the population that we would want to measure. So that ought to be taken into consideration.

Senator SARBANES. Congressman McMillan.

Representative McMILLAN. Thank you, Mr. Chairman.

One of the things that would strike me that would present an aggravating problem would be that if you start trying to differentiate in the Consumer Price Index as applied to entitlements, a possible—maybe a probable—result is that index might be below the average so that there would be times at which the Consumer Price Index for retirees might be below the average CPI-W or the CPI-U and I can imagine the reaction that would occur if that then were applied to programs. And some of the factors that you consider where we've seen wide swings in price levels over the past several years could possibly have produced that in such an index within the past several years.

The other thing that troubles me—I came out of at one point in my life the retail food industry and we know how the then statistics were determined that covered food prices and yet in the marketplace you had constantly shifting patterns of consumption. You had the shift from base commodities to packaged products which built a price factor in real terms into the consumer's pocketbook that weren't necessarily reflected in the statistics, or you had a shift from the consumption of beef to poultry, which people do for health reasons or perhaps for price reasons. These things don't get reflected either.

To what degree would such an index attempt to react to those changes in behavior?

Mrs. NORWOOD. The Consumer Price Index is basically a base weighted index in which we try to isolate price change and it does not, except in a revision, take account of the kinds of switches that you were talking about.

We do have methods of trying to adjust the specific items that we select to take account of that and we do revise the item sample and the outlet sample without changing the weight at the higher levels of aggregation on a 5-year cycle. So one-fifth of the cities in the index are revised each year.

It's interesting to note that during the 1970's this was a major issue and I testified many times before the Congress. It was a major issue because there was the view that because gasoline prices were so high after the oil embargoes that Social Security escalation might be higher than it really needed to be because the CPI had a relatively high weight for gasoline purchases which older Americans purchased less of than the average of the population.

Now, because of the concern for medical care, which Senator Melcher quite properly referred to, there is concern on the other side.

But that's why one has to look at this in terms of the total importance of each of the items in a family's budget. And I believe strongly that—you know, we go out and we price pants, for example, in the clothing component of the CPI, but we also have in that, because the general population purchases them, designer jeans. I don't know what the proportion of designer jeans that an older family would purchase. I doubt that it would be the same as for the population as a whole.

I know that my 89-year-old mother-in-law used to shop by picking up the telephone and calling the store across the street, which was a fairly high-priced store. They delivered. There were services provided because she couldn't get out to the supermarket six or eight blocks away. Those are the kinds of things that we do not now take account of that we would really have to look at if we were to produce an accurate CPI. That would take some time. That would take some considerable research and experimentation.

As I've said, there are reweightings that could be done. They have been done. There have been a dozen studies on this subject thus far. But reweighting does not usually make a great deal of difference. It's the prices that move an index and where you get the prices and what items you select to price. And those are the things that we would really want to look at.

Representative McMILLAN. Thank you.

Senator SARBANES. Well, thank you very much, Commissioner. We appreciate your appearance this morning and your testimony and we look forward to seeing you again next month.

Mrs. Norwood. Thank you very much.

[Whereupon, at 10:25 a.m., the committee adjourned, subject to the call of the Chair.]

EMPLOYMENT-UNEMPLOYMENT

FRIDAY, AUGUST 7, 1987

Congress of the United States, Joint Economic Committee, Washington, DC.

The committee met, pursuant to notice, at 9:30 a.m., in room SD-628, Dirksen Senate Office Building, Hon. Paul S. Sarbanes (chairman of the committee) presiding.

Present: Senators Sarbanes and Melcher, and Representatives Hawkins and McMillan.

Also present: William Buechner, professional staff member.

OPENING STATEMENT OF SENATOR SARBANES, CHAIRMAN

Senator SARBANES. The committee will come to order. We're very pleased this morning to again welcome back before the committee Janet Norwood, the Commissioner of the Bureau of Labor Statistics, recently reappointed and confirmed to another 4-year term.

And the Commissioner will, as is our practice, bring before the committee her regular monthly examination of the employment and unemployment situation in the United States.

Commissioner Norwood, we're pleased to welcome you and your colleagues before the committee again; and we would be happy to hear from you.

STATEMENT OF HON. JANET L. NORWOOD, COMMISSIONER, BUREAU OF LABOR STATISTICS, DEPARTMENT OF LABOR, AC-COMPANIED BY THOMAS J. PLEWES, ASSOCIATE COMMISSION-ER, OFFICE OF EMPLOYMENT AND UNEMPLOYMENT STATIS-TICS; AND KENNETH V. DALTON, ASSOCIATE COMMISSIONER, OFFICE OF PRICES AND LIVING CONDITIONS

Mrs. Norwood. Thank you very much, Mr. Chairman. As usual, I have with me Kenneth Dalton, our price expert, and Tom Plewes, our employment-unemployment expert.

As always, we are very pleased to be here to try to offer a few comments on our press release this morning.

Employment rose in July, and the labor force increased. The total and the civilian unemployment rates—at 5.9 and 6 percent—each sustained the downward trend of recent months. Both rates have dropped by a full percentage point over the last year.

Total civilian employment, as measured by the household survey, rose by 470,000 in July. Payroll employment, as measured by the business survey, rose by about 300,000. In July, industrial activity is usually curtailed and payroll employment declines. This year, those job reductions were much less than usual.

After seasonal adjustment, the manufacturing industry gained 70,000 jobs. This increase occurred despite a decline of nearly 40,000 in automobile manufacturing, which we understand resulted primarily from temporary layoffs related to model changeover and inventory reduction. The BLS diffusion index, which reflects the dispersion of job

The BLS diffusion index, which reflects the dispersion of job growth primarily in manufacturing, rose to 66 percent, a very high level. This improvement occurred even as the factory workweek was maintained at the unusually high level of 41 hours.

This is good news. But, as we have discussed before, we need more than a single month's data to establish a new trend. Over the past year, factory employment has grown by 150,000, but nearly half of that increase occurred in July. Indeed, manufacturing has still only recouped about one-half of the jobs lost during the 1981– 82 recession.

Elsewhere in the goods-producing sector, jobs in the oil and gas extraction industry continued to increase. Employment in this industry has risen slowly but steadily for sometime now, as changes have occurred in the international market for oil and as the price for oil continues to move upward.

The number of jobs in construction held steady from June to July; in fact, construction employment has changed very little over the last 6 months.

As has been the case each month for several years now, employment in the service sector continued upward in July. The number of jobs in the services industry itself rose by 80,000 from June to July—about the average monthly increase we've seen in this industry for sometime now.

Employment in retail trade rose by 60,000, following sluggish performance in May and June. The finance, insurance, and real estate industry continued to gain jobs, but recent increases have been smaller than those of the past few years. The civilian jobless rate, although little changed in July, has

The civilian jobless rate, although little changed in July, has shown marked improvement in recent months. The rate has dropped by seven-tenths of a point in only 5 months. Both adult men and adult women have participated in this improvement. At 5.4 percent, their rates are about half a percentage point lower than they were earlier in the year.

Teenagers, like adults, have also experienced a recent reduction in joblessness; their unemployment rate fell from about 18 percent earlier in the year to July's 15.5 percent.

The jobless rate for Hispanics has improved even faster than those for blacks and for whites.

One problem area in the data for July is that the number of workers employed part time for economic reasons rose by 325,000 to 5.5 million. This series, which had been trending downward in recent months, often fluctuates from one month to the next.

Thus, we really need additional months of data to determine the significance of the July change. The jobless measure with special adjustments for both voluntary and economic part-time labor market experience—that is, U-6 published in our press release—

was 8.3 percent in July, still high, but down a full percentage point from last year.

Changes in the labor force and employment in May, June, and July are usually large and often are quite volatile.

This year's data certainly fit that description. For example, a seasonally adjusted civilian labor force decline of nearly half a million in June was offset by an almost-as-large increase in July.

Such movements often occur because the survey week, which includes the 12th of the month, can start as early as the 6th or as late as the 12th.

Particularly in the summer months when schools close, this timing can have a critical effect on the size of the labor force and employment estimates.

For example, after seasonal adjustment, employment changed little in June and rose by 470,000 in July. The important thing to note, however, is that employment is up by 900,000 since April.

In summary, July's labor market developments were positive. The unemployment rate has improved over the last several months, and strong and widespread employment growth occurred in July.

Mr. Chairman, I'd like to make just a short comment about our productivity data for the second quarter which was released this week.

For the business economy, productivity increased at a much higher rate than in the first quarter—1.3 percent annual rate versus 0.5 percent. While encouraging, the productivity increase in the second quarter reflected gains in output and hours that were smaller than those of the first quarter.

For the year as a whole, only a 0.3 percent productivity gain took place.

Manufacturing continued to do very well, increasing at a rate of 3.3 percent, after a 3-percent gain in the first quarter. For the year as a whole, the increase was 2.8 percent.

This manufacturing experience is very encouraging, because these recent gains are similar to those before the productivity growth slowdown which started in the early 1970's.

The BLS productivity series released this week incorporate the recently revised GNP data. These revisions affected the productivity measures for the last 3 years. The revisions were substantial; with the new GNP data productivity growth is stronger than had previously been reported.

From 1983 through 1986, productivity grew at an annual rate of 2.1 percent for the business economy, in contrast to the previously reported rate 1.3 percent.

reported rate 1.3 percent. One benefit of this more rapid productivity growth is the effect on unit labor costs. Since hourly compensation has risen more slowly than in past recoveries, increasing productivity has contributed to very slow growth in unit labor costs.

In manufacturing, where productivity gains have been most rapid, unit labor costs have actually declined.

As we know, many of our trading partners have been experiencing rising unit labor costs during recent years. When the strong appreciation of the yen and European currencies are taken into account, manufacturing unit labor costs rose over 40 percent in Japan between 1985 and 1986 and about 20 to 40 percent in European countries.

Now, there's additional information corroborating these data on labor cost trends which comes from the recent BLS release on the Employment Cost Index (ECI). Compensation, which includes benefits as well as wages and salaries, in the ECI rose 3.3 percent in the year ending June 1987, compared with a 4-percent gain a year ago.

The 3-percent wage and salary gain for private industry workers was the lowest over-the-year pay gain recorded in the ECI's 11-year history.

Mr. Chairman, we would now be very happy to answer any questions.

Senator SARBANES. Thank you very much, Commissioner, for your usual thorough and comprehensive statement.

[The table attached to Mrs. Norwood's statement, together with the Employment Situation press release, follows:]

Unemployment rates of all civilian workers by alternative seasonal adjustment methods

SOURCE: U.S. DEPARTMENT OF LABOR Bureau of Labor Statistics August 1987 (1) Unadjusted rate. Unemployment rate for all civilian workers, not sessonally adjusted.

(2) <u>Official procedure (X-11 ARIMA method</u>). The published seasonally adjusted rate for all civilian workers. Each of the 3 major civilian labor force components--agricultural employment, nonagricultural employment and unemployment-for 4 age-sex groups--males and females, ages 16-19 and 20 years and over--are seasonally adjusted independently using data from January 1974 forward. The data series for each of these 12 components are extended by a year at each end of the original series using ARIMA (Auto-Regressive, Integrated, Moving Average) models chosen specifically for each series. Each extended series is then seasonally adjusted with the X-11 portion of the X-11 ARIMA program. The 4 teenage unemployment and nonagricultural employments are adjusted with the multiplicative model. The unemployment rate is computed by summing the 4 seasonally adjusted series are revised at the end of each year; Extrapolated factors for January-June are computed at the beginning of each year; extrapolated factors for July-December are computed in the middle of the year after the June data become available. Each set of 6-month factors are published in advance, in the January and July issues.

(3) Concurrent (as first computed, X-11 ARIMA method). The official procedure for computation of the rate for all civilian workers using the 12 components is followed except that extrapolated factors are not used at all. Each component is seasonally adjusted with the X-11 ARIMA program each month as the most recent data become available. Rates for each month of the current year are shown as first computed; they are revised only once each year, at the end of the year when data for the full year become available. For example, the rate for January 1984 would be based, during 1984, on the adjustment of data from the period January 1974 through January 1986.

(4) <u>Concurrent (revised, X-11 ARIMA method)</u>. The procedure used is identical to (3) above, and the rate for the current month (the last month displayed) will always be the same in the two columns. However, all previous months are subject to revision each month based on the seasonal adjustment of all the components with data through the current month.

(5) <u>Stable (X-11 ARIMA method</u>). Each of the 12 civilian labor force components is extended using ARIMA models as in the official procedure and then run through the X-11 part of the program using the stable option. This option assumes that seasonal patterns are basically constant from year-to-year and computes final seasonal factors as unweighted averages of all the seasonal-irregular components for each month across the entire span of the procedure. As in the official procedure, factors are extrapolated in 6-month intervals and the series are revised at the end of each year. The procedure for computation of the rate from the seasonally adjusted components is also identical to the official procedure.

(6) <u>Total (X-11 ARIMA method)</u>. This is one alternative aggregation procedure, in which total unemployment and civilian labor force levels are extended with ARIMA models and directly adjusted with multiplicative adjustment models in the X-11 part of the program. The rate is computed by taking seasonally adjusted total unemployment as a percent of seasonally adjusted total civilian labor force. Factors are extrapolated in 6-month intervals and the series revised at the end of each year.

(7) <u>Residual (X-I) ARIMA method</u>). This is another alternative aggregation method, in which total civilian employment and civilian labor force levels are extended using ARIMA models and then directly adjusted with multiplicative adjustment models. The seasonally adjusted unemployment level is derived by subtracting seasonally adjusted employment from seasonally adjusted labor force. The rate is then computed by taking the derived unemployment level as a percent of the labor force level. Factors are extrapolated in 6-month intervals and the series revised at the end of each year.

(8) <u>12-month extrapolation (X-11 ARIMA method</u>). This approach is the same as the official procedure except that the factors are extrapolated in 12-month intervals. The factors for January-December of the current year are computed at the beginning of the year based on data through the preceding year. The values for January through June of the current year are the same as the official values since they reflect the same factors.

(9) X-11 method (official method before 1980). The method for computation of the official procedure is used except that the series are not excended with ARIMA models and the factors are projected in 12-month intervals. The standard X-11 program is used to perform the seasonal adjustment.

<u>Methods of Adjustment</u>: The X-11 ARIMA method was developed at Statistics Canada by the Seasonal Adjustment and Times Series Staff under the direction of Escela Bee Dagum. The method is described in <u>The X-11 ARIMA Seasonal Adjustment Method</u>, by Escela Bee Dagum, Statistics Canada Catalogue No. 12-564E, February 1980.

The standard X-11 method is described in X-11 Variant of the Census Method II Seasonal Adjustment Program, by Julius Shiskin, Allan Young and John Musgrave (Technical Paper No. 15, Bureau of the Census, 1967).

TRANSMISSION OF MATERIAL IN THIS RELEASE IS EMBARGOED UNTIL

8:30 A.M. (EDT), FRIDAY, AUGUST 7, 1987

THE EMPLOYMENT SITUATION: JULY 1987

Employment rose substantially in July, while unemployment was little changed, the Bureau of Labor Statistics of the U.S. Department of Labor reported today. The overall unemployment rate was 5.9 percent, and the rate for civilian workers was 6.0 percent. Both were a full percentage point lower than a year earlier, with the improvement particularly strong since February.

Total civilian employment--as measured by the monthly survey of households--rose by 470,000 in July. The number of nonagricultural payroll jobs--as measured by the monthly survey of establishments--was up by 300,000. Over the past year, the two employment series have advanced by 2.8 and 2.5 million, respectively.

Unemployment (Household Survey Data)

Both the number of unemployed persons, 7.2 million in July, and the civilian unemployment rate, 6.0 percent, were little changed from June, after seasonal adjustment. Similarly, jobless rates for adult men and women (both at 5.4 percent), teenagers (15.5 percent), whites (5.1 percent), blacks (12.6 percent), and Hispanics (7.9 percent) all showed little change between June and July. Over the past year, however, unemployment rates dropped considerably for all these worker groups. (See tables A-2 and A-3.)

The number of persons jobless for 15 weeks or more fell by about 150,000 in July to 1.9 million, the lowest level since June 1980. The average (mean) duration of unemployment fell from 14.8 weeks in June to 14.0 weeks in July. (See table A-7.)

Civilian Employment and the Labor Force (Household Survey Data)

Civilian employment rose by 470,000 in July to 112.7 million on а seasonally adjusted basis. Over the year, enployment increased by 2.8 million, with adult women accounting for 1.4 million of the gain, adult men for 1.2 million, and teenagers for 200,000. (See table A-2.)

The civilian labor force increased by about 435,000 in July, after seasonal adjustment, following a drop of similar magnitude in the previous month. Prior to seasonal adjustment, very large labor force increases typically occur in the April-to-July period, as young people leave school and enter the summer job market. This often results in uneven

Table A. Major indicators of labor market activity, seasonally adjusted

month-to-month changes in the labor force, even after seasonal adjustment. During this year's summer expansion period, the labor force was up about 600,000 after seasonal adjustment. (See table A-2.)

Industry Payroll Employment (Establishment Survey Data)

Total nonagricultural employment rose by about 300,000 in July to 102.1 million, after seasonal adjustment. This increase followed 2 months of slow job growth in business establishments. While the service-producing sector accounted for most of the over-the-month employment increase, as it usually does, job gains were also widespread in manufacturing industries, after seasonal adjustment. (See table B-1.)

In the goods-producing sector, manufacturing employment rose by 70,000, to 19.1 million in July. This gain occurred despite an employment decline of 40,000 in motor vehicles and equipment, primarily reflecting model changeover and inventory adjustments. Construction employment was unchanged in July and has experienced little movement, on a seasonally adjusted basis, since January. The number of jobs in mining and its oil and gas extraction component edged up, continuing a recent trend of small employment gains.

In the service-producing sector, the services industry rose by 80,000 in July, paced by a 35,000 gain in its health services component. Employment in retail trade advanced by 60,000, following 2 months of little change. The finance, insurance, and real estate industry continued to expand, gaining 20,000 jobs in July.

Weekly Hours (Establishment Survey Data)

The average workweek of production or nonsupervisory workers on private nonagricultural payrolls edged down 0.1 hour in July to 34.7 hours, seasonally adjusted. Manufacturing hours remained at very high levels. The workweek was at 41.0 hours for the third month in a row, and factory overtime edged back up to 3.8 hours. (See table B-2.)

The index of aggregate weekly hours of production or nonsupervisory workers on private nonagricultural payrolls increased 0.3 percent to 120.3 (1977=100), seasonally adjusted. Reflecting July's employment gains, the manufacturing index rose by 0.5 percent to 93.7. (See table B-5.)

Hourly and Weekly Earnings (Establishment Survey Data)

Average hourly earnings and average weekly earnings were little changed on a seasonally adjusted basis in July. Prior to seasonal adjustment, hourly earnings decreased by 1 cent to \$8.91, and weekly earnings were down 35 cents to \$311.85. (See table B-3.) .

The Hourly Earnings Index (HEI) was 173.2 (1977=100) in July, seasonally adjusted, an increase of 0.2 percent from June. For the 12 months ended in July, the increase was 2.4 percent. The HEI excludes the effects of two types of changes unrelated to underlying wage rate movements--fluctuations in manufacturing overtime and interindustry employment shifts. In dollars of constant purchasing power, the HEI decreased 1.4 percent during the 12-month period ended in June. (See table B-4.)

The Employment Situation for August 1987 will be released on Friday, September 4, at 8:30 A.M. (EDT).

Explanatory Note

This news release presents statistics from two major surveys, the Current Population Survey (household survey) and the Current Employment Statistics Survey (establishment survey). The household survey provides the information on the labor force, total employment, and unemployment that appears in the A tables, marked HOUSEHOLD DATA. It is a sample survey of about 59,500 households that is conducted by the Bureau of the Census with most of the findings analyzed and published by the Bureau of Labor Statistics (BLS).

The establishment survey provides the information on the employment, hours, and earnings of workers on nonagricultural payrolls that appears in the B tables, marked ESTABLISHMENT DATA. This information is collected from payroll records by BLS in cooperation with State agencies. The sample includes over 290,000 establishments employing over 38 million people.

For both surveys, the data for a given month are actually collected for and relate to a particular week. In the household survey, unless otherwise indicated, it is the calendar week that contains the 12th day of the month, which is called the survey week. In the establishment survey, the reference week is the pay period including the 12th, which may or may not correspond directly to the calendar week.

The data in this release are affected by a number of technical factors, including definitions, survey differences, seasonal adjustments, and the inevitable variance in results between a survey of a sample and a census of the entire population. Each of these factors is explained below.

Coverage, definitions, and differences between surveys

The sample households in the household survey are selected so as to reflect the entire civilian noninstitutional population 16 years of age and older. Each person in a household is classified as employed, unemployed, or not in the labor force. Those who hold more than one job are classified according to the job at which they worked the most hours.

People are classified as *employed* if they did any work at all as paid civilians; worked in their own business or profession or on their own farm; or worked 15 hours or more in an enterprise operated by a member of their family, whether they were paid or not. People are also counted as employed if they were on unpaid leave because of illness, bad weather, disputes between labor and management, or personal reasons. Members of the Armed Forces stationed in the United States are also included in the employed total.

People are classified as unemployed, regardless of their eligibility for unemployment benefits or public assistance, if they meet all of the following criteria: They had no employment during the survey week; they were available for work at that time; and they made specific efforts to find employment sometime during the prior 4 weeks. Persons laid off from their former jobs and awaiting recall and those expecting to report to a job within 30 days need not be looking for work to be counted as unemployed.

The labor force equals the sum of the number employed and the number unemployed. The unemployment rate is the percentage of unemployed people in the labor force (civilian plus the resident Armed Forces). Table A-5 presents a special grouping of seven measures of unemployment based on varying definitions of unemployment and the labor force. The definitions are provided in the table. The most restrictive definition yields U-1 and the most comprehensive yields U-7. The overall unemployment rate is U-5a, while U-5b represents the same measure with a civilian labor force base.

Unlike the household survey, the establishment survey only counts wage and salary employees whose names appear on the payroll records of nonagricultural firms. As a result, there are many differences between the two surveys, among which are the following:

- The household survey, although based on a smaller sample, reflects a larger segment of the population; the establishment survey excludes agriculture, the self-employed, unpaid family workers, private household workers, and members of the resident Armed Forces;

- The household survey includes people on unpaid leave among the employed; the establishment survey does not;

- The household survey is limited to those 16 years of age and older; the establishment survey is not limited by age;

 The household survey has no duplication of individuals, because each individual is counted only once; in the establishment survey, employees working at more than one job or otherwise appearing on more than one payroll would be counted separately for each appearance

Other differences between the two surveys are described in "Comparing Employment Estimates from Household and Payroll Surveys," which may be obtained from the BLS upon request.

Seasonal adjustment

Over the course of a year, the size of the Nation's labor force and the levels of employment and unemployment undergo sharp fluctuations due to such seasonal events as changes in weather, reduced or expanded production, harvests, major holidays, and the opening and closing of schools. For example, the labor force increases by a large number each June, when schools close and many young people enter the job market. The effect of such seasonal variation can be very large: over the course of a year, for example, seasonality may account for as much as 95 percent of the month-to-month changes in unemployment.

Because these seasonal events follow a more or less regular pattern each year, their influence on statistical trends can be eliminated by adjusting the statistics from month to month. These adjustments make nonseasonal developments, such as declines in economic activity or increases in the participation of women in the labor force, easier to spot. To return to the school's-out example, the large number of people entering the labor force each June is likely to obscure any other changes that have taken place since May, making it difficult to determine if the level of economic activity has risen or declined. However, because the effect of students finishing school in previous years is known, the statistics for the current year can be adjusted to allow for a comparable change. Insofar as the seasonal adjustment is made correctly, the adjusted figure provides a more useful tool with which to analyze changes in economic activity.

Measures of labor force, employment, and unemployment contain components such as age and sex. Statistics for all employees, production workers, average weekly hours, and average hourly earnings include components based on the employer's industry. All these statistics can be seasonally adjusted either by adjusting the total or by adjusting each of the components and combining them. The second procedure usually yields more accurate information and is therefore followed by BIS. For example, the seasonally adjusted figure for the labor force is the sum of eight seasonally adjusted civilian employment components, plus the resident Armed Forces total (not adjusted for seasonality), and four seasonally adjusted unemployment components; the total for unemployment is the sum of the four unemployment components; and the overall unemployment rate is derived by dividing the resulting estimate of total unemployment by the estimate of the labor force.

The numerical factors used to make the seasonal adjustments are recalculated regularly. For the household survey, the factors are calculated for the January-June period and again for the July-December period. The January June period is applied to data that have been published over the previous 5 years. For the establishment survey, updated factors for seasonal adjustment are calculated only once a year, along with the introduction of new benchmarks which are discussed at the end of the next section.

Sampling variability

Statistics based on the household and establishment surveys are subject to sampling error, that is, the estimate of the number of people employed and the other estimates drawn from these surveys probably differ from the figures that would be obtained from a complete census, even if the same questionnaires and procedures were used. In the household survey, the amount of the differences can be expressed in terms of standard errors. The numerical value of a standard error depends upon the size of the sample, the results of the survey, and other factors. However, the numerical value is always such that the chances are approximately 68 out of 100 that an estimate based on the samele will differ by no more than the standard error from the results of a complete census. The chances are approximately 90 out of 100 that an estimate based on the sample will differ by no more than 1.6 times the standard error from the results of a complete census. At approximately the 90-percent level of confidence—the confidence limits used by BLS in its analyses—the error for the monthly change in total employment is on the order of plus or minus 328,000; for total unemployment it is 220,000; and, for the overall unemployment rate, it is 0.19 percentage point. These figures do not mean that the sample results are off by these magnitudes but, rather, that the chances are approximately 90 out of 100 that the "true" level or rate would not be expected to differ from the estimates by more than these amounts.

Sampling errors for monthly surveys are reduced when the data are cumulated for several months, such as quarterly or annually. Also, as a general rule, the smaller the estimate, the larger the sampling error. Therefore, relatively speaking, the estimate of the size of the labor force is subject to less error than is the estimate of the number unemployed. And, among the unemployed, the sampling error for the jobless rate of adult men, for example, is much smaller than is the error for the jobless rate of teenagers. Specifically, the error on monthly change in the jobless rate for men is .26 percentage point; for teenagers, it is 1.25 percentage points.

In the establishment survey, estimates for the 2 most current months are based on incomplete returns; for this reason, these estimates are labeled preliminary in the tables. When all the returns in the sample have been received, the estimates are revised. In other words, data for the month of September are published in preliminary form in October and November and in final form in December. To remove errors that build up over time, a comprehensive count of the employed is conducted each year. The results of this survey are used to establish new benchmarks—comprehensive counts of employment–against which month-to-month changes can be measured. The new benchmarks also incorporate changes in the classification of industries and allow for the formation of new establishments.

Additional statistics and other information

In order to provide a broad view of the Nation's employment situation, BLS regularly publishes a wide variety of data in this news release. More comprehensive statistics are contained in *Employment and Earnings*, published each month by BLS. It is available for \$85.00 per issue or \$22.00 per year from the U.S. Government Printing Office. Washington, D.C., 20204. A check or money order made out to the Superintendent of Documents must accompany all orders.

Employment and Earnings also provides approximations of the standard errors for the household survey data published in this release. For unemployment and other labor force categories, the standard errors appear in tables B through J of its "Explanatory Notes." Measures of the reliability of the data drawn from the establishment survey and the actual amounts of revision due to benchmark adjustments are provided in tables M. O. P. and O of that nublication.

¹ Data relate to production workers in mining and manufacturing; to construction workers in construction; and to nonsupervisory workers in transportation and public utilities; wholease and reall track (nance, insurance, and real eaties; and services. These groups account for approximately four-fifths of the total employees on private nongricultural payrolis.

,

¹ This series is not published sessonally adjusted since the sessonal component is small mistive to the trend-cycle and/or impular components and consequently cannot be separated with sufficient precision. p = preliminary.

.

NOTE: Figures are the percent of industries with employment rising. (Half of the un-changed components are counted as rising.) Data are centered within the spans

Senator SARBANES. I want to direct some questions to you at the end of our hearing with you this morning that bear on the hearing that's to follow.

They deal with the 1990 census and the Office of Management and Budget's proposal to cut a significant number of questions from that census.

But before we turn to that, we obviously need to explore the report you've just given us.

I'll yield to Congressman McMillan to begin the questioning.

Representative McMILLAN. Thank you, Mr. Chairman. And, welcome again, Mrs. Norwood.

Mrs. Norwood. Thank you.

Representative McMILLAN. You mentioned in your statement revision of GNP figures that changed significantly, productivity figures in manufacturing.

Would you be a little bit more explicit in terms of what revisions were made and what period that covered?

Mrs. Norwood. The GNP data have been revised for the last 3 years. And to generate the productivity data, of course, we rely on the output information that comes from the GNP.

It is my understanding that the largest part of the 3-year revision was for 1986. A good part of the revision was in personal consumption expenditures, which is probably related in many ways to the retail sales data and another part was related to the trade data. And then there were some other changes that were made.

Representative McMillan. Two areas that I think we've-one in particular we've focused on in the past. You mentioned that construction employment had been steady for the first 6 months of this year?

Mrs. Norwood. That's correct.

Representative McMILLAN. Is that in seasonally adjusted figures, or absolute figures?

Mrs. Norwood. That's seasonally adjusted.

Representative McMILLAN. Would that be a normal trend in construction, or would we normally, even with seasonal adjustment, expect some increase?

Mrs. NORWOOD. That's somewhat flatter than we would have expected. If you go back several years, we had increases that were fairly substantial, say 20,000 to 35,000. This is probably related to the declines in the last few months in housing starts; although housing permit information suggests that there is going to be a pickup in the future.

Representative McMILLAN. We really had two things impacting construction. I suppose, particularly housing, some uptick in interest rates, plus—— Mrs. Norwood. Yes.

Representative McMILLAN [continuing]. Some argue that the Tax Reform Act has had some effect on new starts in construction. And I suppose that would impact housing as well.

But it would strike me, given those two factors, that performances remained essentially strong, given those-

Mrs. NORWOOD. But has not declined

Representative McMILLAN. That's correct. And has not declined from a very solid, high level of performance.
The other area had to do with teenagers. Could you comment on teenage unemployment within the first 6 months of this year relative to comparable periods?

Because that's been one area that's been of particular concern to all of us.

Mrs. Norwood. There has been considerable improvement in the unemployment data for teenagers. The July rate is 15.5 percent, although that bounces around a good bit. You need data over several months in order to understand what's going on.

And we have to understand, too, that it is a relatively small group, so we need more than a full percentage point change for it to be statistically significant.

Since February, there has been a considerable decline. The unemployment rate for teenagers in February was 18 percent, is now down to 15.5 percent.

As you know, during the months of May and June, we're always a little hesistant to put a great deal of emphasis on the teenager data. The July data are probably more reflective of the situation and are probably more correct.

So that's a very good sign, I think.

Representative McMILLAN. One additional question. You may not have these figures at the top of your head, but could you characterize the unemployment rate at this stage in this economic expansion in contrast to other expansions in the post-World War II period?

Mrs. Norwood. The unemployment rate—well, the current recovery period, which of course has extended a very long time now—56 months—has been characterized by a very strong reduction in unemployment.

And that reduction in unemployment has been considerably larger both in absolute terms, of course, and in percentage terms, than in most of the previous recessions.

The unemployment has gone down. For example, from March 1975 to November 1979, which is the comparable period of the recovery after the 1973-75 recession, unemployment went down by 21.8 percent.

In the current recovery, the last 56 months of recovery, unemployment declined by 39.5 percent. So there's a much greater decline.

Now, part of that is because the labor force increased much less in this recovery than in the past recovery because we have moved through a good bit of the baby boom generation's entrance into the labor force.

Representative McMILLAN. I think, as we pointed out in the past, I think that speaks well for the economy because much of this has occurred in the face of over a 2- to 3-year period of substantially increased imports into this country, which it would be expected would have a negative impact on job creation.

So the economy has been able to—not that we like that, but able to overcome that to a great extent.

Mrs. Norwood. We clearly are seeing a restructuring of employment in this country away from manufacturing, particularly durable manufacturing, toward the service-producing sector. That's been going on for some years now. Representative McMILLAN. Thank you very much.

I yield back the balance of my time.

Senator SARBANES. Thank you very much, Congressman.

Commissioner, let me ask you one question on the unemployment figures before I turn to the question of the 1990 census.

You say in your statement that the number of workers working part time for economic reasons—in other words, workers who wanted to work full time, but couldn't find full-time work and, therefore, were taking part-time jobs—rose by 325,000.

Mrs. Norwood. That's correct.

Senator SARBANES. Is that the figure that is set against the figure at the top of the second page in terms of the increase in total civilian employment?

Mrs. Norwood. It's related, certainly. There are and there have always been a large number of people who are working part time, and some of them want full-time jobs.

The difference this month is that that figure, which is still fairly high—it's over 5 million—was trending downward for several months.

This month, there was a jump in the number of those people. And as I have said, I'm not sure whether that jump will be sustained or not, but it is something that I would rather see continue to head downward.

Senator SARBANES. If you look at the increase in employment, is 325,000 of that increase the increase in part-time employment?

Mr. PLEWES. It doesn't work out exactly. A good part of the increase in part-time jobs this month was due to an increase in part time for economic reasons. So, it's not completely fair to characterize the increase in overall employment as being driven entirely by part-time factors. But, there is that factor.

Mrs. NORWOOD. Fourteen-plus million people are working part time because that's what they want to do. It appears from this month's numbers that in addition, 5.5 million workers said that they really want full-time work.

And we don't know how lasting that will be. We'll really have to wait for a few months to see.

Senator SARBANES. Before you depart, since the Bureau of Labor Statistics is vitally concerned with the quantity and quality of our statistical data, I'd like to put a couple of questions to you.

We are going to hold, as you may know, a hearing immediately after we conclude this one on the possible effects of the proposal by the Office of Management and Budget to drop from the 1988 census dress rehearsal—in other words, the preparation for the 1990 census—a large number of questions that had been hitherto scheduled for inclusion.

This obviously raises some serious concerns about the comprehensiveness and the quality of the Federal statistical base. And we'll be going into that in some detail.

I'm sure you're aware that the proposal would delete a number of questions from the 1990 census, including questions relating to housing and employment.

Obviously, the BLS is a heavy user of information that comes from census questions.

Do you have any perception now of how the statistical programs of the BLS might be affected by the proposals for the 1990 census? Mrs. Norwood. Yes, I do, Mr. Chairman.

Let me say first that the Bureau of Labor Statistics staff has over the last 3 years been working with an interagency group that has involved both OMB and the Census Bureau on issues related to data in the census.

I can tell you that early in that period, the Bureau of Labor Statistics proposed a number of additional questions for the census. We lost out on many of those because the decision was that the burden on respondents would be too great.

I certainly understand the need to be extraordinarily careful both about the overall overloading of the Census Bureau questionnaire and also about the need to be certain that data are really needed for the entire sample or for smaller samples.

It is my understanding that OMB has requested further justification of certain questions.

All of those questions affect the BLS programs. Several of them, however, affect two very important programs very severely. And I'd like to comment very briefly on those.

Either the elimination or reduction of the number of people who would be asked the questions on housing and, in particular, question 31B on the number of weeks worked, would severely affect the Consumer Price Index program.

The number of weeks worked, for example, is one of the parts of the definition of the wage earner/clerical worker group for the urban wage earner and clerical worker, CPI.

We would----

Senator SARBANES. Would you pull that microphone a little closer?

Mrs. Norwood. I'm sorry.

Senator SARBANES. Maybe if you moved your notebook there.

Mrs. Norwood. Yes. We would not be able to define---

Senator SARBANES. That's much better.

Mrs. Norwood [continuing]. The wage earner clerical worker group without the question 31B on the number of weeks worked unless we were to change the definition. And that's a definition that has been in place since World War I.

There are a series of housing questions which involve things like the value of the house, the year built, the rent value, and so on, which are used as variables in the selection of the expenditure survey sample.

The expenditure survey is used, as you know, as the basis of the CPI weights and of CPI item sample. Our estimate is that without the needed housing questions there probably would be about a 50-percent reduction in the reliablity of that survey. That would require us to expand the consumer expenditure survey considerably. That, of course, would increase that burden on respondents, and we think the cost could be some \$10 million plus.

And that estimate, by the way, is one that we had made long before this became a critical issue today. So it was not a hasty estimate that was made just overnight. In addition, we conduct a survey of housing in order to get both owner-occupied housing and rental housing for both CPI's, the urban index and wage earner index.

For that survey, our procedure is to select the units through clusters of city blocks in the individual areas in order to increase the sample efficiency.

Without the data gained from several of the questions under discussion, we would have to increase our housing sample work enormously.

I'm informed that we now do somewhat less than 500,000 units; in order to get the same reliability, we would have to increase that to somewhere between 3 and 6 million units.

In addition, we use information on utilities, the type of utilities, the type of heating in the CPI program.

The other program that would be very severely affected by the elimination or reduction in many of these questions, particularly those on employment and unemployment, is our local area unemployment statistics program.

As you know, we at the Bureau of Labor Statistics are required by law to develop unemployment estimates for 5,400 geographic areas. And that includes States. It includes statistical areas. It includes all the counties of the country and all cities that have a population of 25,000 or more.

For those purposes, we use the detailed census data by detailed geography in order to be able to derive the employment and unemployment data, as well as data by class of worker, and the number of people with a job but not at work. These data are needed in order to have geographic area data that are consistent with the national unemployment data.

As you know, these geographic area data are important. They are used to allocate funds as well as to trigger on and off a number of programs. And, of course, I don't need to tell you that they have some political significance in local areas and States.

We use the information obtained from the census to adjust data for place of work and place of residence, since the national definition of unemployment is based upon where people live, not necessarily where they work. And we also would need these data to just aggregate information in order to produce the data for the smaller areas of the country.

Now, there are a lot of other ways in which we use data from the census. They are used in the productivity program. They're used in our occupational outlook program. The employment data are used to weigh the employment cost index.

They are used in an industry occupational matrix, which we produce in our Federal-State cooperative program which the States use in order to develop projections of the future.

I don't believe that those uses are as important as the uses for the two programs that I have described. In those cases, the data needed are absolutely critical. And we are preparing further justifications to send to OMB. And it is my hope that we will not have a problem in continuing to obtain these data.

Senator SARBANES. Let me ask just a question on the process. BLS is part of the interagency group. Is that correct?

Mrs. Norwood. Yes, we are.

Senator SARBANES. How large is the interagency group?

Mrs. Norwood. Well, Tom Plewes has been representing us.

Mr. PLEWES. I don't know the number of agency representatives.

It's more than a dozen. I think that OMB can better address that. Senator SARBANES. Does OMB chair the group?

Mr. PLEWES. That's correct, yes.

Senator SARBANES. Well, we obviously will probe this with them. But I understand that this proposal to drop 30 questions from the dress rehearsal comes fairly late in the process.

Has there not been an extended process going on literally over a number of years?

Mrs. Norwood. Yes.

Senator SARBANES. Leading toward the 1990 census and trying to develop a questionnarie?

Mrs. Norwood. Yes, these issues have been discussed for some 2 to 3 years. And there has in fact been some testing of some of these questions. And it has come as something of a surprise that further justification is required.

But we will make that justification. And we have every hope that they will be considered.

Senator SARBANES. Senator Melcher.

Senator MELCHER. No questions.

Senator SARBANES. Congressman Hawkins.

Representative HAWKINS. No questions. Thank you.

Senator SARBANES. Well, Commissioner, we're pleased to have you back before us this morning. We thank you very much for your testimony.

Mrs. Norwood. Thank you, Mr. Chairman.

Senator SARBANES. We'll take just about a 2-minute break while we prepare for the hearing on the census, 1990 census issue.

[Whereupon, at 10:07 a.m., the committee adjourned, subject to the call of the Chair.]

EMPLOYMENT-UNEMPLOYMENT

FRIDAY, SEPTEMBER 4, 1987

Congress of the United States, Joint Economic Committee,

Washington, DC.

The committee met, pursuant to notice, at 9:32 a.m., in room SD-628, Dirksen Senate Office Building, Hon. William Proxmire (member of the committee) presiding.

Present: Senator Proxmire.

Also present: William Buechner, professional staff member.

OPENING STATEMENT OF SENATOR PROXMIRE, PRESIDING

Senator PROXMIRE. This morning the Joint Economic Committee is very pleased to welcome Janet Norwood, Commissioner of the Bureau of Labor Statistics, who will testify on the employment and unemployment situation for August 1987.

According to the unemployment figure released today, the unemployment rate in August remained at 6 percent, the same level as in July. Both employment and the labor force grew by about 350,000, after seasonal adjustment.

Even though there was no change in the overall unemployment rate, the unemployment rate for adults declined slightly in August and went up half a percentage point for teenagers.

The total number of people unemployed was 7.2 million, no improvement at all from the July level. All the new jobs created in August were in service-producing industries with no new jobs in manufacturing.

Overall, then, the August employment figures suggest that the economy is continuing to expand at a slow but steady rate, with almost all of the economy's growth concentrated in the service sectors.

Before you begin, Mrs. Norwood, Senator D'Amato has requested that his opening statement be placed in the record. He had another commitment and is unable to be present.

[The written opening statement of Senator D'Amato follows:]

(75)

WRITTEN OPENING STATEMENT OF SENATOR D'AMATO

Good morning, Mr. Chairman. I would also like to welcome the Commissioner of Labor Statistics, Dr. Janet Norwood. Commissioner Norwood, I am most interested in your observations on August employment figures.

• As we all know, last month vou reported to this committee July's employment figures that were at their lowest since the end of 1979. You reported that the total civilian employment stood at 112,730,000, an all-time record. An impressive increase of 470,000 in just one month's time. The unemployment rate in July dropped 0.2 percentage points to 6.0 percent over June's figure of 6.1 percent. Last month's figure showed a decrease of one percentage point over July of 1986 figure of 7.0 percent.

Your report showed a sign of continued strength in our economy through expansion and creation of new jobs. These figures exceeded the expectations of most economic forecasters.

For the month of August, the unemployment rate remained unchanged from July's figures. The number of individuals employed, as shown by business payrolls, increased by approximately 355,000.

In the State of New York, the unemployment rate for the month of August decreased by .2% over the previous month to 4.3 percent. Overall, Dr. Norwood, these figures paint a bright employment picture in our nation.

76

For the past vear, the employment situation in this nation has been very stable. Unemployment remains steady around 6.3 to 6 percent. Employment levels are at an all time high. This is due in no small part to the lower interest rates and lower inflation that have resulted from the President's economic program. However, the level of employment not only reflects the general health of the economy and specific industries, but also the increase or decrease in the number of Americans bringing home paychecks and their ability to make purchases. Therefore, we must also be aware of the drop in the value of the dollar and its impact on the American worker. Americans need both jobs and good salaries to provide for themselves and their families.

It is my hope that your testimony today will provide additional encouraging information.

Thank you, Mr. Chairman.

Senator PROXMIRE. The committee will now turn to Commissioner Norwood for analysis of the August employment and unemployment data. Then I have some questions on this data because I think it is indicative of some interesting changes in the economy. Go right ahead.

STATEMENT OF HON. JANET L. NORWOOD, COMMISSIONER, BUREAU OF LABOR STATISTICS, DEPARTMENT OF LABOR, AC-COMPANIED BY THOMAS J. PLEWES, ASSOCIATE COMMISSION-ER, OFFICE OF EMPLOYMENT AND UNEMPLOYMENT STATIS-TICS; AND KENNETH V. DALTON, ASSOCIATE COMMISSIONER, OFFICE OF PRICES AND LIVING CONDITIONS

Mrs. Norwood. Thank you very much, Mr. Chairman. Before reading my statement, let me say that I believe that this is my 92d appearance.

Senator PROXMIRE. Your 92d? That is 92 months.

Mrs. NORWOOD. That's right. Ninety-two. Ninety-second appearance before this committee.

Senator PROXMIRE. You don't look a day over 25. [Laughter.] Mrs. Norwood. Thank you.

And you, Mr. Chairman, have been on the other side of the table for nearly all of them, often as presiding officer. I am aware that you have given notice of your plans to engage in other pursuits beginning in 1989.

I would like to tell you that I shall miss you, not because you have always made me feel comfortable behind this table; quite the contrary. At times you have put me on the spot with your searching and incisive questions, and you were always prepared to pursue any response that did not seem complete.

You have always been supportive of a democratic society's need for objective data and of our efforts to produce data of high quality. The Nation's statistical system has had no stronger champion. Those of us who serve in that system will always be in your debt, and I want to thank you.

Senator PROXMIRE. Thank you, Mrs. Norwood. That is a most gracious statement. I hope that everybody in Wisconsin is watching. [Laughter.]

Mrs. Norwood. I have with me, as always, Kenneth Dalton on my right, who is our price expert, and Tom Plewes on my left, who is our expert on employment and unemployment data.

As always, we are very, very pleased to be here to provide a few comments to supplement our press release this morning.

The labor market improvements of recent months held in August. Employment rose, and the labor force increased. Both the civilian unemployment rate, at 6 percent, and the overall rate, including resident Armed Forces, at 5.9 percent, were unchanged from July. Both rates have declined substantially since the beginning of the year and are 0.8 of a percentage point below the level of a year ago.

Total employment, as measured by the household survey, rose by 355,000 from July to August, bringing the employment-population ratio to a new high of 61.8 percent. Payroll employment, as meas-

ured by the business survey, grew by a much smaller amount, however—only 155,000.

Virtually all of the increase in payroll jobs from July to August was in the service-producing sector. Employment in the services industry itself rose by 90,000, with strong growth in both business and health services. The number of factory jobs, which had increased by 90,000 in the previous month, held steady in August. Moreover, both weekly hours and overtime hours in the Nation's factories continued to be very high by historical standards.

The BLS diffusion index, which is heavily weighted toward manufacturing, was lower than in July but, at 55 percent in August, showed that a considerable number of industries added to their work forces in August.

The data for August marked the 57th month of the current recovery, one of the longest peacetime expansions in our history. During this period, from November 1982 to August 1987, close to 14 million jobs have been added, most of them in service-producing industries. The largest gains occurred in the services industry itself, retail trade, and finance, insurance and real estate.

About 1 million jobs were added in manufacturing, but that industry has still only regained about 45 percent of the jobs lost during the 1981-82 recession. Five manufacturing industries lumber, furniture, transportation equipment, printing and publishing, and rubber and plastics—now employ considerably more workers than at the July 1981 prerecession speak, but eight industries primary metals, nonelectrical machinery, instruments, tobacco, apparel, chemicals, petroleum and coal, and leather manufacturing actually have lost employment since the end of the recession.

When we compare the labor market progress of the current recovery period to the comparable period from March 1975 to December 1979, we find a number of interesting differences. The labor force has grown, but much more slowly than in the 1970's because of more modest growth in the working-age population and in the rate of labor force participation.

Employment has grown considerably during the current recovery, but the pace has been somewhat slower than in the 1975-79 period. The largest difference between the two periods is in the industrial distribution of that growth. While the service-producing sector has grown at about the same rate during the current recovery as in the 1975-79 one, the number of factory jobs has grown far more slowly—by 5.7 percent in the 1982-87 period compared to 15.3 percent in the 1975-79 period.

Another indicator of the difference between the current expansion and that of the late 1970's is the relatively high number of persons working part time for economic reasons. You will recall that last month we reported an increase in this number and cautioned that additional months of data were needed to interpret the significance of the change. We now see a return of this measure to its May to June level of 5.3 million. These "partially unemployed" workers are disproportionately black and female.

In summary, recent improvements in unemployment held up in August. Further employment gains occurred in services, while July's increase in factory jobs was sustained.

Mr. Chairman, my colleagues and I will be glad to try to answer any questions you may have. [The table and charts attached to Mrs. Norwood's statement, to-gether with the Employment Situation press release, follow:]

Unem ployment rates of all civilian workers by alternative seasonal adjustment methods

SOURCE: U.S. DEPARTMENT OF LABOR Bureau of Labor Statistics September 1987 81

•

(1) Unadjusted rate. Unemployment rate for all civilian workers, not seasonally adjusted.

(2) Official procedure (X-11 ARIMA method). The published seasonally adjusted rate for all civilian workers. Each of the 3 major civilian labor force components--agricultural employment, nonagricultural employment and unemployment. -for 4 age-sex groups--males and females, ages 16-19 and 20 years and over-are seasonally adjusted independently using data from January 1974 forward. The data series for each of these 12 components are extended by a year at each end of the original series using ARIMA (Auto-Regressive, Integrated, Moving Average) models chosen specifically for each series. Each extended series is then seasonally adjusted with the X-11 portion of the X-11 ARIMA program. The 4 teenage unemployment and nonagricultural employment components are adjusted with the additive adjustment model, while the other components are adjusted with the multiplicative model. The unemployment rate is computed by summing the 4 seasonally adjusted unemployment components and calculating that total as a percent of the civilian labor force total derived by summing all 12 seasonally adjusted components. All the seasonally adjusted series are revised at the end of each year. Extrapolated factors for January-June are computed at the beginning of each year; extrapolated factors for July-December are computed in the middle of the year after the June data become available. Each set of 6-month factors are published in advance, in the January and July issues, respectively, of Employment and Earnings.

(3) Concurrent (as first computed, X-11 ARTMA method). The official procedure for computation of the rate for all civilian workers using the 12 components is followed except that extrapolated factors are not used at all. Each component is seasonally adjusted with the X-11 ARIMA program each month as the most recent data become available. Rates for each month of the current year are shown as first computed; they are revised only once each year, at the end of the year when data for the full year become available. For example, the rate for January 1974 through January 1984.

(4) <u>Concurrent (revised, X-11 ARIMA method)</u>. The procedure used is identical to (3) above, and the rate for the current month (the last month displayed) will always be the same in the two columns. However, all previous months are subject to revision each month based on the seasonal adjustment of all the components with dat through the current month.

(5) <u>Stable (X-11 ARIMA method)</u>. Each of the 12 civilian labor force components is extended using ARIMA models as in the official procedure and then run through the X-11 part of the program using the stable option. This option assumes that seasonal patterns are basically constant from year-to-year and computes final seasonal factors as unweighted averages of all the seasonal-irregular components for each month across the entire span of the period adjusted. As in the official procedure, factors are extrapolated in 6-month intervals and the series are revised at the end of each year. The procedure for computation of the rate from the seasonally adjusted components is also identical to the official procedure.

(6) <u>Total (X-11 ARIMA method)</u>. This is one alternative aggregation procedure, in which total unemployment and civilian labor force levels are extended with ARIMA models and directly adjusted with multiplicative adjustment models in the X-11 part of the program. The rate is computed by taking seasonally adjusted total unemployment as a percent of seasonally adjusted total civilian labor force. Factors are extrapolated in 6-month intervals and the series revised at the end of each year.

(7) <u>Residual (X-i1 ARIMA method</u>). This is another alternative aggregation method, in which total civilian employment and civilian labor force levels are extended using ARIMA models and then directly adjusted with multiplicative adjustment models. The seasonally adjusted unemployment level is derived by subtracting seasonally adjusted employment from seasonally adjusted labor force. The rate is then computed by taking the derived unemployment level as a percent of the labor force level. Factors are extrapolated in 6-month intervals and the series revised at the end of each year.

(8) <u>12-month extrapolation (X-11 ARIMA method</u>). This approach is the same as the official procedure except that the factors are extrapolated in 12-month intervals. The factors for January-December of the current year are computed at the beginning of the year based on data through the preceding year. The values for January through June of the current year are the same as the official values since they reflect the same factors.

(9) X-11 method (official method before 1980). The method for computation of the official procedure is used except that the series are not extended with ARIMA models and the factors are projected in 12-month intervals. The standard X-11 program is used to perform the seasonal adjustment.

<u>Methods of Adjustment</u>: The X-11 ARIMA method was developed at Statistics Canada by the Seasonal Adjustment and Times Series Staff under the direction of Estela Bee Dagum. The method is described in <u>The X-11 ARIMA Seasonal Adjustment Method</u>, by Estela Bee Dagum, Statistics Canada Catalogue No. 12-564E, February 1980.

The standard X-11 method is described in X-11 Variant of the Census Method II Seasonal Adjustment Program, by Julius Shiskin, Allan Young and John Musgrave (Technical Paper No. 15, Bureau of the Census, 1967).

TRANSMISSION OF MATERIAL IN THIS RELEASE IS EMBARGOED UNTIL 8:30 A.M. (EDT), FRIDAY,

Employment rose in August and unemployment was unchanged, the Bureau of Labor Statistics of the U.S. Department of Labor reported today. The overall unemployment rate and the civilian worker rate remained at 5.9 and 6.0 percent, respectively. Both rates have declined by 0.7 percentage point since the beginning of this year.

THE EMPLOYMENT SITUATION: AUGUST 1987

Total civilian employment--as measured by the monthly survey of households--rose by 355,000 in August after seasonal adjustment. Nonfarm payroll employment--as measured by the monthly survey of establishments--was up by 155,000.

Unemployment (Household Survey Data)

The number of unemployed persons was unchanged at 7.2 million in August, after seasonal adjustment, as were the jobless rates for nearly all major labor force groups. The rates for adult men (5.2 percent), adult women (5.3 percent), teenagers (16.0 percent), whites (5.1 percent), blacks (12.4 percent), and Hispanics (8.0 percent) showed over-the-month change. (See tables A-2 and A-3.) little or

The length of unemployment was also little changed in August. The average (mean) duration of unemployment was about unchanged at 14.3 weeks, while the median duration edged down slightly to 6.4 weeks. (See table A-7.)

The number of employed persons part tíme for economic reasons--sometimes referred to as the partially unemployed--declined in August to 5.3 million, returning to the May-June levels. Although this figure has edged down slightly thus far in 1987, it remains relatively high by historical standards. (See table A-4.)

Civilian Employment and the Labor Force (Household Survey Data)

Civilian employment declined less than usual in August and, after seasonal adjustment, advanced by 355,000 to 113.1 million. Most of this increase occurred among teenagers. The proportion of the population that is employed rose 0.2 percentage point to a new high of 61.8 percent. (See table A-2.)

The civilian labor force increased to 120.3 million in August, after seasonal adjustment, with the labor force participation rate edging up to 65.7 percent. Over the past year, the labor force has grown by 2.1 million, with about half of the increase occurring among adult women.

Industry Payroll Employment (Establishment Survey Data)

Total nonagricultural employment rose by 155,000 in August to a seasonally adjusted level of 102.3 million. Virtually all of the job growth occurred in the service-producing sector. (See table B-1.)

Within the service sector, the services industry component continued its strong job expansion, increasing by 90,000 in August. Over the year, 1 million jobs have been added in the industry. As usual, health and business services accounted for most of the over-the-month gain. Job growth continued in finance, insurance, and real estate as employment advanced by 25,000 over the month. Employment in retail and wholesale trade was about unchanged from July levels.

In the goods-producing sector, manufacturing employment was unchanged in August, following a substantial increase (90,000) in July. Employment in automobiles rose by 20,000, after declining by 30,000 in July (seasonally adjusted). Most of the recent employment fluctuations in this industry result from early plant shutdowns for model changeover and extended layoffs for inventory reductions. In contrast, employment in apparel and other textile products declined by 20,000, a return to the June level. Construction employment was unchanged at 5.0 million in August. Mining and its oil and gas extraction component continued the gradual recovery from the job losses of the 1985-86 period.

Weekly Hours (Establishment Survey Data)

The average workweek of production or nonsupervisory workers on private nonagricultural payrolls expanded by 0.2 hour after seasonal adjustment, reaching 35.0 hours. Most of this increase occurred in retail trade and wholesale trade. Manufacturing hours remained at 41.0 for the fourth consecutive month, and overtime hours were unchanged from July at 3.8, both historically high levels. (See table B-2.)

The index of aggregate weekly hours of production or nonsupervisory workers on private nonagricultural payrolls increased 0.5 percent in August to 121.2 (1977=100), seasonally adjusted. The manufacturing index was about unchanged at 93.7. (See table B-5.)

Hourly and Weekly Earnings (Establishment Survey Data)

Average hourly earnings rose 0.8 percent in August, while average weekly earnings rose 1.4 percent, seasonally adjusted. Before seasonal adjustment, average hourly earnings rose by 4 cents to \$8.95, and average weekly earnings were up \$4.09 to \$315.94. Over the year, hourly earnings were up 25 cents and weekly earnings rose \$10.57.

The Hourly Earnings Index (Establishment Survey Data)

The Hourly Earnings Index (HEI) was 173.9 (1977-100) in August, seasonally adjusted, an increase of 0.4 percent from July. For the 12 months ended in August, the increase was 2.6 percent. The HEI excludes the effects of two types of changes unrelated to underlying wage rate movements--fluctuations in manufacturing overtime and interindustry employment shifts. In dollars of constant purchasing power, the HEI decreased 1.4 percent during the 12-month period ended in July. (See table B-4.)

The Employment Situation for September 1987 will be released on Friday, October 2, at 8:30 A.M. (EDT).

Explanatory Note

This news release presents statistics from two major surveys, the Current Population Survey (household survey) and the Current Employment Statistics Survey (establishment survey). The household survey provides the information on the labor force, total employment, and unemployment that appears in the A tables, marked HOUSEHOLD DATA. It is a sample survey of about 59,500 households that is conducted by the Bureau of the Census with most of the findings analyzed and published by the Bureau O Labor Statistics (BLS).

The establishment survey provides the information on the employment, hours, and earnings of workers on nonagricultural payrolls that appears in the B tables, marked ESTABLISHMENT DATA. This information is collected from payroll records by BLS in cooperation with State agencies. The sample includes over 290.000 establishments employing over 38 million people.

For both surveys, the data for a given month are actually collected for and relate to a particular week. In the household survey, unless otherwise indicated, it is the calendar week that contains the 12th day of the month, which is called the survey week. In the establishment survey, the reference week is the pay period including the 12th, which may or may not correspond directly to the calendar week.

The data in this release are affected by a number of technical factors, including definitions, survey differences, seasonal adjustments, and the inevitable variance in results between a survey of a sample and a census of the entire population. Each of these factors is explained below.

Coverage, definitions, and differences between surveys

The sample households in the household survey are selected so as to reflect the entire civilian noninstitutional population 16 years of age and older. Each person in a household is classified as employed, unemployed, or not in the labor force. Those who hold more than one job are classified according to the job at which they worked the most hours.

People are classified as *employed* if they did any work at all as paid civilians; worked in their own business or profession or on their own farm; or worked 15 hours or more in an enterprise operated by a member of their family, whether they were paid or not. People are also counted as employed if they were on unpaid leave because of illness, bad weather, disputes between labor and management, or personal reasons. Members of the Armed Forces stationed in the United States are also included in the employed total.

People are classified as unemployed, regardless of their eligibility for unemployment benefits or public assistance, if they meet all of the following criteria: They had no employment during the survey week; they were available for work at that time; and they made specific efforts to find employment sometime during the prior 4 weeks. Persons laid off from their former jobs and awaiting recall and those expecting to report to a job within 30 days need not be looking for work to be counted as unemployed.

The labor force equals the sum of the number employed and the number unemployed. The unemployment rate is the percentage of unemployed people in the labor force (civilian plus the resident Armed Forces). Table A-5 presents a special grouping of seven measures of unemployment based on varying definitions of unemployment and the labor force. The definitions are provided in the table. The most restrictive definition yields U-1 and the most comprehensive yields U-7. The overall unemployment rate is U-5a, while U-5b represents the same measure with a civilian labor force base.

Unlike the household survey, the establishment survey only counts wage and salary employees whose names appear on the payroll records of nonagricultural firms. As a result, there are many differences between the two surveys, among which are the following:

 The household survey, although based on a smaller sample, reflects a larger segment of the population; the establishment survey excludes agriculture, the self-employed, unpaid family workers, private household workers, and members of the resident Armed Forces;

- The household survey includes people on unpaid leave among the employed; the establishment survey does not;

- The household survey is limited to those 16 years of age and older; the establishment survey is not limited by age;

— The household survey has no duplication of individuals, because each individual is counted only once; in the establishment survey, employees working at more than one job or otherwise appearing on more than one payroll would be counted vepariately for each appearance.

Other differences between the two surveys are described in "Comparing Employment Estimates from Household and Payroll Surveys," which may be obtained from the BLS upon request.

Seasonal adjustment

Over the course of a year, the size of the Nation's labor force and the levels of employment and unemployment undergo sharp fluctuations due to such seasonal events as changes in weather, reduced or expanded production, harvests, major holidays, and the opening and closing of schools. For example, the labor force increases by a large number each June, when schools close and many young people enter the job market. The effect of such seasonal variation can be very large; over the course of a year, for example, seasonality may account for as much as 95 percent of the month-to-month changes in unemployment.

Because these seasonal events follow a more or less regular pattern each year, their influence on statistical trends can be eliminated by adjusting the statistics from month to month. These adjustments make nonseasonal developments, such as declines in economic activity or increases in the participation of women in the labor force, easier to spot. To return to the school's-out example, the large number of people entering the labor force each June is likely to obscure any other changes that have taken place since May, making it difficult to determine if the level of economic activity has risen or declined. However, because the effect of students finishing school in previous years is known, the statistics for the current year can be adjusted to allow for a comparable change. Insofar as the seasonal adjustment is made correctly, the adjusted figure provides a more useful tool with which to analyze changes in economic activity.

Measures of labor force, employment, and unemployment contain components such as age and sex. Statistics for all employees, production workers, average weekly hours, and average hourly earnings include components based on the employer's industry. All these statistics can be seasonally adjusted either by adjusting the total or by adjusting each of the components and combining them. The second procedure usually yields more accurate information and is therefore followed by BLS. For example, the seasonally adjusted figure for the labor force is the sum of eight seasonally adjusted civilian employment components, plus the resident Armed Forces total (not adjusted for seasonality), and four seasonally adjusted unemployment components; the total for unemployment is the sum of the four unemployment components; and the overall unemployment rate is derived by dividing the resulting estimate of total unemployment by the estimate of the labor force.

The numerical factors used to make the seasonal adjustments are recalculated regularly. For the household survey, the factors are calculated for the January-tune period and again for the July-December period. The January trevision is applied to data that have been published over the previous 5 years. For the establishment survey, updated factors for seasonal adjustment are calculated only once a year, along with the introduction of new benchmarks which are discussed at the end of the next section.

Sampling variability

Statistics based on the household and establishment surveys are subject to sampling error, that is, the estimate of the number of people employed and the other estimates drawn from these surveys probably differ from the figures that would be obtained from a complete census, even if the same questionnaires and procedures were used. In the household survey, the amount of the differences can be expressed in terms of standard errors. The numerical value of a standard error depends upon the size of the sample, the results of the survey, and other factors. However, the numerical value is always such that the chances are approximately 68 out of 100 that an estimate based on the sample will differ by no more than the standard error from the results of a complete census. The chances are approximately 90 out of 100 that an estimate based on the sample will differ by no more than 1.6 times the standard error from the results of a complete census. At approximately the 90-percent level of confidence—the confidence limits used by BLS in its analyses—the error for the monthly change in total employment is on the order of plus or minus 328,000; for total unemployment it is 220,000; and, for the overall unemployment rate, it is 0.19 percentage point. These figures do not mean that the sample results are off by these magnitudes but, rather, that the chances are approximately 90 out of 100 that the "true" level or rate would not be expected to differ from the estimates by more than these amounts.

Sampling errors for monthly surveys are reduced when the data are cumulated for several months, such as quarterly or annually. Also, as a general rule, the smaller the estimate, the larger the sampling error. Therefore, relatively speaking, the estimate of the size of the labor force is subject to less error than is the estimate of the number unemployed. And, among the unemployed, the sampling error for the jobless rate of adult men, for example, is much smaller than is the error for the jobless rate of trenagers. Specifically, the error on monthly change in the jobless rate for men is .26 percentage point; for teenagers, it is 1.25 percentage points.

In the establishment survey, estimates for the 2 most current months are based on incomplete returns; for this reason, these estimates are labeled preliminary in the tables. When all the returns in the sample have been received, the estimates are revised. In other words, data for the month of September and published in preliminary form in October and November and in final form in December. To remove errors that build up over time, a comprehensive count of the employed is conducted each year. The results of this survey are used to establish new benchmarks—comprehensive counts of mensured. The new benchmarks also incorporate changes can be measured. The new benchmarks also incorporate changes in the classification of industries and allow for the formation of new establishments.

Additional statistics and other information

In order to provide a broad view of the Nation's employment situation, BLS regularly publishes a wide variety of data in this news release. More comprehensive statistics are contained in *Employment and Earnings*, published each month by BLS. It is available for \$8.50 per issue or \$22.00 per year from the U.S. Government Printing Office, Washington, D.C., 20204. A check or money order made out to the Superintendent of Documents must accompany all orders.

Employment and Earnings also provides approximations of the standard errors for the household survey data published in this release. For unemployment and other labor force categories, the standard errors appear in tables B through J of its "Explanatory Notes." Measures of the reliability of the data drawn from the establishment survey and the actual amounts of revision due to benchmark adjustments are provided in tables M, O, P, and Q of that publication.

*Data relate to production workers in mining and menufacturing; to construction workers in construction; and to nonsuparisory workers in transportation and public tilities; wholesale and retail trade; finance, insurance, and near estats; and services. These groups account for approximately four-fifths of the total employees on private nonagricultural pervola. *This series is not published seasonally adjutted since the seasonal component is small relative to the trend-cycle and/or imagular components and consequently cannot be separated with sufficient precision.

¹ Number of employees, seasonally adjusted for 1, 3, and 8 month spana, on payrolis of 185 rivete nonagricultural industries. Data for the 12-month span are unadjusted. p = preliminary.

NOTE: Figures are the percent of industries with employment rising. (Half of the un-changed components are counted as rising.) Data are centered within the spans.

Senator PROXMIRE. Thank you very much, Commissioner Norwood, for your usually highly competent summary of the developments over the last month in the employment and unemployment situation.

You have a table that showed a fascinating difference between the recovery that took place after the 1974-75 recession and the recession of 1982. What it showed was that the civilian labor force total increased much more and much more rapidly in the earlier period; that is, between March 1975 and December 1979, it increased 13 million, according to your data that I have in front of me, and in this latest recovery the increase in the labor force has been only about 9 million.

Now, does that mean that if we had the same increase in the labor force in the past 4 or 5 years that we had in the 1975-79 period, we would now have about 4 million more people out of work and have an unemployment rate of about 9 percent. In other words, much of this recovery has been because the work force has not grown as rapidly as it did in the previous recovery.

Mrs. Norwoon. The work force has not grown as much, in large part because the growth of population has slowed down. Had that population growth continued, there probably would have been more stimulation of the economy.

I think it is clear that it has been much easier for us to have a reduced unemployment rate, given the slowdown in labor force growth, but I do not think that we can reverse that statement and say that all of the difference would have been found among the unemployment. It has clearly been a much easier situation.

The other point is that we have had many fewer youngsters, particularly teenagers entering the work force, which brings about, in a sense, a downward pull on the unemployment rate.

Senator PROXMIRE. But it seems to me it is fair to say we would have had somewhat higher unemployment, probably, if we had not had the decline in the rate of growth of the work force.

had the decline in the rate of growth of the work force. Now, during the first half of 1987, nonfarm productivity rose at an annual rate of just under 1 percent. But it rose; productivity rose. But real wages fell by 1.3 percent. Why did real wages fall, even though productivity went up? In

Why did real wages fall, even though productivity went up? In other words, people are more productive. They are producing more per hour worked, but their wages are going down. That is hard for me to understand.

I would also like to ask you if workers didn't benefit, and they obviously did not from their increased productivity, who did?

• Mrs. Norwood. One of the things that is happening particularly in manufacturing and certainly with farm products is that we are holding the line on prices in the case of farm products. In many cases some products are being sold at lower prices than before.

So some of these productivity gains are being seen in a rationalization of industry, reductions in cost, and lower prices. Some of it, however, is probably going into increased profits.

Senator PROXMIRE. Now, workers' real average weekly earnings fell 0.3 percent in July. That was the fifth decline in the past 7 months. Over the past year, real wages have declined 1.2 percent. In fact, since July 1978, the buying power of the average American workers has nosedived 11.6 percent. Would you comment on the lower real earnings statistics? Is there something here in the statistics that we are missing? Is this an unfair description of what is happening to workers' income, or is there some interpretation I am missing here?

Mrs. Norwood. It is clear from the average earning series that workers' earnings, on average, are not keeping up with inflation. If we look, however, at our employment cost index, particularly that part of it which includes fringe benefits, we find that the civilian nonfarm population has an increase over the year of about 3.3 percent and the CPI from July to July 3.9 percent. So they are close.

I think that that is a better comparison, but it clearly shows that workers' earnings have not kept up most recently with the increase in inflation. That is partly because of the turnaround in oil prices.

Senator PROXMIRE. Let me ask you about something you mentioned in your statement that you made to us this morning. You pointed out what seems to me really an astonishing fact; that in some areas there is actually less employment than there was at the depth of the last recession.

Mrs. Norwood. That is right.

Senator PROXMIRE. Some of those are in my State. But is there any particular area of the country that has particularly suffered from this and is probably worse off than it was? Would this be the case in Louisiana, Texas, and Oklahoma?

Mrs. Norwood. The oil extraction industry, of course, has affected some of the areas of the southwest. The north central part of the country and the south central part of the country have been affected, particularly by apparel and textiles and by some of the heavy durable manufacturing—the decline in nonelectrical machinery, for example, and transportation equipment and some of the feeder industries that are located there.

One of the points that is of some interest, of course, is that in some of these cases, particularly apparel, for example, the declines in employment are really a continuation of a trend that has been going on since the 1940's and 1950's. Some of the declines, of course, are quite new.

Senator PROXMIRE. I suppose the American people are about as disturbed about the merchandise trade deficit as anything. The people I talk to in Wisconsin certainly are; I think that is true generally. They are concerned about the fact that we are importing so much from abroad, exporting so little, and that we are exporting jobs in effect. We hear this constantly, not only from labor people but from business people, too, very widely.

The merchandise trade deficit reached still another all-time record of \$39.5 billion in the second quarter. That deficit has achieved record levels in six of the last seven quarters.

With your knowledge of import and export prices and the drop in the dollar, the spectacular drop in the dollar really, can you give us any insights into why, so long after the decline in the value of the dollar, our international balance of payments position just doesn't improve?

I know there is a J, but that J seems to be an awfully long one before it is going up.

Mrs. NORWOOD. Yes, it is. The J curve certainly has been considerably extended, much more than most economists expected. I think there are a lot of reasons for it.

First, it is quite clear that although import prices have increased, many of our trading partners, particularly the Japanese, have absorbed large portions of that increase. They have been reducing their profits in order to maintain their market shares. So I think that is one point.

Second, there has been a considerable restructuring of U.S. trade with other countries. We are getting a much larger proportion of our trade now from places like Korea and Taiwan and other places which have their currencies pegged to the U.S. dollar. So their prices are not really affected by any drop in the value of the dollar.

Third, during the whole period of the 1970's and leading up to the difficulties we have now, I think there has been some decline in our competitive structure and we have had many manufacturing industries which have become somethat inefficient and high cost. It will take some time for them to turn around. Some of them are beginning to do that, but that will take some time.

During that period into the 1980's, with very high value of the dollar, many companies began out-sourcing production so that there are many facilities abroad, and it is unlikely that much of that will be brought back to this country but, if so, it will be done really fairly slowly.

So'I think that there are a number of reasons for this. The trade balance picture, I think, is improving and I expect it to improve further. But I think it is going to be a lot slower than most people had expected.

Senator PROXMIRE. A lot slower.

Mrs. Norwood. Yes.

Senator PROXMIRE. So it might be, you think, several more months, maybe a year or two before we get the benefits of the lower dollar

Mrs. Norwood. I think that the crucial issue is really the response that American producers make. Senator PROXMIRE. I don't hear you say much about the deficit,

the Federal deficit, the fiscal deficit.

Do you think that plays a significant role, too? Lots of people argue that that is a central factor.

Mrs. Norwood. Clearly it has been. It has an important effect, as you know better than I, on the influx and the inflow of foreign funds to this country because essentially what we are doing is having foreigners support our economy because of our own deficits. So that clearly has a very important effect. Senator PROXMIRE. As you know, the Occupational Safety and

Health Administration has recently been ordered by the U.S. courts to expand its program of letting workers know they have been exposed to dangerous substances. Congress is also working on legislation in that important worker safety and health area.

Can you supply us with any statistics on how the problem of worker exposure to dangerous substances is growing? Are you satisfied with the quality of the statistics in that field and do you have any proposal to improve them?

Mrs. Norwood. I am not satisfied at all with the quality of the data in the safety and health field. We have been reviewing our data. We have three basic sources of data. One is an annual survey of business establishments. The second is development of administrative data from workers' compensation records. And the third is a series of surveys on work injuries that we do ourselves in cooperation with the States.

We have, with your help, Mr. Chairman, contracted with the National Academy of Sciences' Committee on National Statistics. They have appointed a rather outstanding panel of experts to review the entire data system. They have completed their work and we are expecting by about the end of October to have their report. I anticipate that they will recommend a number of changes. We ourselves would like to see a number of changes and we will certainly share that report with you and others in the Congress as well as with the general public and our advisory committees.

well as with the general public and our advisory committees. On the subject of the high-risk notification, essentially, there is really very little data. It is very difficult even to recognize some of these problems. Even physicians are having difficulty recognizing many of these problems.

We are, however, undertaking a special survey, a work injury survey, looking at the effects on workers of the inhalation of dangerous substances, and that work has just begun. It will involve identification of cases by the States from their workers' comp records, and then a follow back to the workers themselves to find out exactly what has happened. So that work is underway.

We are also contracting with the National Center for Health Statistics and we have been cooperating with NIOSH to add some questions to the health interview survey so that we can get at the other side of this. We have a survey of business establishments. We would like to be able to compare those data with a survey of the workers themselves. And we have some other ideas which we will be presenting through the budget process at the proper time.

What we are really doing right now is waiting for the report which should be coming out fairly soon from the National Academy of Sciences and I do expect that to be critical and constructive. That is why we went to them because we felt that we really needed to have expert advice.

Senator PROXMIRE. Mrs. Norwood, as you mentioned in your statement, the percentage of the population that is employed today of the total population, of the population over 16 years of age and noninstitutional, is higher than it has ever been. In other words, a higher proportion of people are actually working than before, which is certainly good news.

But, as your chart shows, the improvement in the employment population ratio has occurred only among adult women. A big part of this is women coming into the work force still continuing to come in. From staying at home and being homemakers, they have entered into the work force as never before in our history, with adult men and teenagers still far below past records.

Why has the employment population ratio failed to improve for adult men and for teenagers?

Mrs. Norwood. Apparently because of the problems that we are seeing in the industrial restructuring of the economy. Many of the

adult men are working in manufacturing industries. We are seeing a number of plants closing down and we are seeing a complete restructuring of activity and we are also seeing the need for retraining of many of these people because the kinds of jobs that they had before are no longer going to be jobs in the future.

Senator PROXMIRE. May I just interrupt?

The statistics that were just given to me indicate that since 1954, from 1951-54 for instance, the percentage of men 20 years and over, noninstitutional, who were working was above 85 percent, between 85-90 percent. And it is now down to less than 75 percent. So there has been a consistent drop.

Mr. PLEWES. There is really not much to add there. That is absolutely correct. It has gone down long term. I think that one of the things that is interesting is that in the last year or two after the recession, it has stopped going down. It has not gone up, but at least it has stopped going down.

Senator PROXMIRE. Since 1975, it has been about the same, but it was around 75 percent; now it's below 75 percent. But you are right. It is about the same.

Mr. PLEWES. A very large part of that was early retirement, and the early retirement trend has slowed down, at least in the last couple of years. But during that whole period that you are quoting, a large part of that was early retirement.

Mrs. Norwood. One of the interesting points that can be made about that also is the fact that men are retiring earlier, but women who have come into the labor force much later are staying in the labor force much longer, so we are not seeing at the older age cohort, the retirements for women that we are seeing for men because women have not built up their retirement.

Senator PROXMIRE. Is that because in many programs they don't qualify until they have worked a number of years and they have to get their years in? If they start at the age of 50, obviously they have to be older before they can retire.

Mrs. Norwood. That is right. Obviously, some of that is going to change. Some two or three decades from now, I think that the data will show something somewhat different.

Senator PROXMIRE. Your chart 7 shows that the number of longterm unemployed is still higher than at any time during the peaks of the last two recessions. Two million people have been unemployed for 4 months or longer.

What are the characteristics of the long-term unemployed? That is really the most tragic unemployed, the kind of unemployment that causes terrible disruptions and trauma.

Is the United States creating a class of people who are unemployable and simply cannot find jobs, even in a tight labor market?

Mrs. Norwood. We clearly have a large group who have been unemployed for 6 months or more. There are more than 1 million of them, 1,100,000 of them. They are disproportionately minority. They get into a situation where they need retraining. Their educational levels often are relatively low.

There really needs to be, in my view, a renewed effort in this country to strengthen the basic educational system so that workers will be in a position to take the kind of training that they need. I am very concerned about those groups. I believe that the American labor market is a very dynamic one and that most people who have a spell of unemployment usually manage to find a job or engage in some other activity fairly easily, and though they suffer some difficulties during the period of unemployment, they often receive unemployment insurance and they make out.

It is those who, month after month after month, remain unemployed that we need to be very concerned about.

Senator PROXMIRE. In July, both the Consumer Price Index and the Producer Price Index rose only 0.2 percent. That was a much smaller rise than these indexes were showing earlier in the year.

What accounted for the slowdown in the inflation rate and is there any evidence that it will continue?

Mrs. Norwood. The inflation rates have for a long time been very much affected by energy prices and by food prices and they will probably continue to be. Food prices jump up and down, depending sometimes on the weather and sometimes, as you well know, on conditions on the farm and decisions that are made about livestock and plantings.

The energy prices have been slowing down. The slowdown is a little bit less than occurred last year, but they have been slowing down since then.

Perhaps Mr. Dalton would like to comment further.

Senator PROXMIRE. Mr. Dalton.

Mr. DALTON. Specifically in July, both the Producer Price Index and the Consumer Price Index experienced lower food prices and that accounted for the smaller increase in July.

Senator PROXMIRE. But that is seasonally adjusted, isn't it? Mr. DALTON. Yes, it is.

But through the first 7 months of the year, the CPI has risen at an annual rate of 5 percent, with energy prices rising at an annual rate of 14.3 percent. In contrast, in 1986, energy prices declined almost 20 percent. So the big difference this year is pretty clearly energy.

Mrs. Norwood. And the big issue there, of course, is that energy prices are very much dependent on conditions in the Persian Gulf, so the future of inflation is in part at least dependent on what happens there and the effect of that activity on the price of oil.

Senator PROXMIRE. In spite of the fact that we get a very small proportion of our oil from the Persian Gulf, less than 6 percent, I understand. Of course, we have a glut of oil in this country that we can't produce, and that is the problem in Alaska and Louisiana and so forth.

Mrs. Norwood. Somewhat higher priced.

Senator PROXMIRE. Between April and July, the civilian unemployment rate fell from 6.3 to 6 percent. These are months when seasonal factors can distort the unemployment figures.

Now that we have the August data, can you discern any unusual seasonal factors in the data that may have affected the unemployment picture this past summer?

Mrs. Norwood. We think that the August data are fairly stable and represent what is actually happening. We were concerned, in July in particular, about some of the developments that occurred. The August increase in the household survey which was very large and I think perhaps somewhat overstated was largely for teenagers. And I think that is something that bears watching. The establishment survey is showing considerably more moderate growth than the household survey. And the seasonals are somewhat different for the two surveys, in part because of the various activities of youngsters and in part because during the summer months there are still a lot of unpaid vacations, so people are off the payroll during the summer months. This means that the seasonal adjustment factors are somewhat different—in fact they go in different directions—for the two surveys.

Senator PROXMIRE. In addition to the regular budget figures, the Congressional Budget Office publishes—and I quote—a Standardized Employment Deficit which eliminates the influence of recessions on the deficit by calculating the Federal deficit that would occur at a constant 6 percent unemployment rate. Currently the unemployment rate is 6 percent which is the figure used by CBO.

Does that mean that we can't count on additional cyclical improvements in the economy to have any further impact on the deficit unless the unemployment rate falls below 6 percent, in which case many people would say then we have to start putting on the brakes and having a tighter monetary policy, and we are going to have an inflation and the stock market begins to fall and so forth?

Mrs. NORWOOD. I am not at all sure that there is that direct a relationship between a further drop in the unemployment rate and what is really considered to be an increase in inflation. It is quite clear that the Phillips curve relationship has shifted considerably in recent years.

Senator PROXMIRE. So that we can stand a lower unemployment rate than we could before?

Mrs. Norwood. I like to think so.

Senator PROXMIRE. All of us would like to think so, but what is your professional judgment?

Mrs. Norwood. We will have to wait and see. [Laughter.]

Senator PROXMIRE. Okay. Go ahead.

Mrs. NORWOOD. I am not really familiar with all of the details of the CBO study. I am rather impressed with the fact—and I can't resist saying this—that it is almost impossible even to look at the Federal Government's deficit without using Bureau of Labor Statistics data.

You will forgive that plug.

Senator PROXMIRE. I think that is a good plus, I support it.

The last time the unemployment rate was 6 percent was in December 1979. A recent study by Dennis Roth of the Congressional Research Service argues that these figures are not comparable because of significant changes that have occurred in the labor market since then. For example, the proportion of people working part time has risen from 14 percent to 17.5 percent. The number of adult males working part time involuntarily has grown 62 percent. The unemployment rate for adult men, particularly black men, is much higher now than in 1979.

How would you compare a 6-percent unemployment rate today to a 6-percent unemployment rate in 1979 with those figures in mind? Mrs. Norwood. That would be very difficult to do; 1979 was a year of increasing inflation also, and we need to keep that in mind it seems to me.

We had had most of the very massive increase of women coming into the labor market. Since that time, however, we have had quite a big increase in Hispanic entrants into the labor market. The Hispanic population of the country has gotten larger. We are seeing rather interesting trends for Hispanics now. Their labor force entrance is much larger even than the black minority and many of them are becoming employed. In fact, one out of every three new jobs is going to a Hispanic. So I think that is a very real difference.

I am not sure that I have very much more to add.

Senator PROXMIRE. According to an article in the August 1987 Monthly Labor Review, the growth in defense spending that occurred between 1980 and 1985, which was very, very big, as we know—that created 600,000 additional manufacturing jobs in defense-related industries.

During that time, overall manufacturing employment fell by 1 million jobs, implying that 1.6 million jobs were lost in nondefense manufacturing industries.

What do these new figures say about the strength of the nondefense manufacturing industry during that period, particularly in view of the fact that many people expect that we are going to have a flattening out at best in the defense procurement area? As you know, Congress has had to put on the brakes, and has put on the brakes pretty sharply.

Mrs. Norwood. It is very clear that defense expenditures have stimulated the job market. One of the things that has always fascinated me about defense expenditures is that one of the largest effects on jobs is in eating and drinking places. As you spend money for defense, you increase the cafeterias and the restaurant meals and so on.

Senator PROXMIRE. Sale of beer?

Mrs. Norwood. Yes.

On the other hand, the data suggest that durable manufacturing has not done as well as I would have expected. A good bit of the jobs in manufacturing that have been held and some of them that have been recouped have been in some of the nondurable jobs as well. Nonelectrical machinery, for example, is not really doing terribly well.

We seem to have housing-related manufacturing, like lumber and wood and furniture manufacturing, some of the appliances. They have held up, as has construction, though that is flattening out now because of the changes in interest rates.

Senator PROXMIRE. One school of thought holds that U.S. manufacturing industries are not in trouble because the manufacturing share of GNP has been relatively constant.

Does the BLS study suggest that this relatively constant share of GNP masked two trends: First, an increase in manufacturing output caused by the rise in defense spending which obscured a strong secular decline which we would otherwise have seen in nondefense industries? Mrs. Norwood. Clearly, the defense spending helped employ-ment in manufacturing. I don't think there is any doubt about that.

What would have happened in the absence of that probably is that we wouldn't have quite the same deficit position that we have and therefore our trade position and a number of other things might be different. So it is a little bit hard to look at that.

Senator PROXMIRE. But overall, the likelihood is that we would

have had a decline in manufacturing. Mrs. Norwood. I believe so; yes. I think that is a trend that has been continuing for a very long time. It has just been much more rapid during the 1980's than before.

Senator PROXMIRE. According to the August 31 productivity release from the Bureau of Labor Statistics, manufacturing productivity grew 4.9 percent at an annual rate during the second quarter. That was a large upward revision from the August 3 preliminary figures that showed a 3.3-percent increase in manufacturing productivity.

What factors account for the upward revision in manufacturing productivity? Is it normal for the revision to be that large? That seems to me a very large adjustment.

Mrs. Norwood. It was a very large adjustment. We revise our productivity figures when the gross national product accounts figures are revised, and there was a rather large revision in GNP data. That does give us some cause for concern, but we have to measure output and that is done in the best way possible by the Bureau of Economic Analysis.

Senator PROXMIRE. A 4.9-percent rise in manufacturing productivity in the second quarter resulted from a 3.4-percent increase in output, combined with a 1.5-percent decline in hours worked, according to the August 31 productivity release.

Monthly employment figures show that manufacturing employment went up 40,000 in the second quarter, and average weekly hours declined only two-tenths of 1 percent, from 41 to 40.9 hours.

What accounts for the 1½ percent decline in average weekly hours that was used to compute manufacturing productivity?

Mrs. Norwood. First of all, the productivity data are built upon a much broader base than the production worker data that we produced here or that you were talking about, and it includes all people who are employed.

Senator PROXMIRE. Within a month or two, the current expansion will overtake the 1975-80 expansion as the longest peacetime period without a recession. In terms of job growth, labor force growth and other measures of the strength of the economy, how does this expansion compare with the 1975-80 expansion and how does it compare for various groups in the labor force, such as women, blacks, and teenagers?

Mrs. Norwood. It does not compare as well. There has been, as we discussed earlier, a slowdown in labor force growth that has really been quite marked; 8.3 percent, for example, in the 1980's, compared to 14.1 percent in the 1975-79 period.

Employment has done a bit better-14 percent compared to 17 percent. Because of the combination of these factors, in particular the reduction in growth of the labor force, unemployment has declined markedly.

As for the different groups of the population, employment of women has been about the same in the current recovery period as in the past in terms of percentage growth.

The labor force growth of women has slowed down, however. It is continuing and I believe will continue to grow, but at a much slower pace. The black labor force has been growing at a somewhat slower pace, not nearly as much of a reduction in the rate of growth, however, as for the white population, and a larger proportion of the blacks have found jobs.

Senator PROXMIRE. Now let me ask you the question that really concerns me very much. That is, that it seems to be that it is no accident that when we talk about the extension of recovery, we talk about peace periods.

In war periods, we have had a much longer recovery. We had that in World War II. As you know, the Vietnam war is the other big example.

Now, I argue that in view of the massive deficits we have run, that are very comparable to the kind of deficits you might run in a war period, \$200 billion deficits and close to it back to back, that they have had a real effect in extending this recovery period. And to the extent that we do what we should do and what I am sure you agree we should do, which is reduce those deficits as promptly and sharply as we can, it is going to have a slowdown effect on the economy.

Mrs. Norwood. I don't think there is any doubt about that.

Senator PROXMIRE. Would you agree that one of the reasons why we have had this long, long recovery is because we have had this fiscal policy that has been stimulated?

Mrs. Norwoon. Clearly, as you yourself indicated earlier, the increase in defense expenditures has had an important effect on the labor market and I think it is important to take that into account. It is hard to know what would have happened in the absence of that development.

Senator PROXMIRE. One more question on minimum wage, unemployment, and inflation. Minimum wage is before the Senate, as you know. We may act on it. I am very supportive of an increase in the minimum wage. We have not had one for 6 years, and meanwhile the cost of living has gone up 27 percent. These are the poorest working people in our country and I think it is grossly unjust.

Every labor expert seems to have a strong view on the consequence of raising minimum wages. However, the conclusions of these experts range from no effects on employment and inflation to the loss of many jobs, especially for teenagers, and a serious increase in inflation.

I made a recent, very cursory study, which indicated that the minimum wage on the basis of experience historically has had a favorable effect as it has been increased.

The last time we had very, very high unemployment was when we had the first introduction—the minimum wage terminated that. In 1938, we had an unemployment of 17 percent. We put in the minimum wage and it was never that high again. I also tried to check it out on the basis of the decades when we have had an increase in the minimum wage. We had it in the 1960's, a decline in the 1970's, and a decline in the minimum wage of course, effective minimum wage, the real minimum wage in the 1980's because inflation was so great and the minimum wage did not increase in the 1980's and it increased very little in the 1970's.

I find those seem to coincide with higher levels of unemployment. So I would like to know your conclusion as to what effect an action by the Congress to increase the minimum wage, as has been proposed, I think moderately and gradually over a period of years, what effect that might have on unemployment.

Mrs. Norwood. I really can't answer that question precisely. We have done a study in which we have looked at recent empirical studies that have been carried out by economists on the minimum wage.

Senator PROXMIRE. Can you make that available? I would like to see that study.

Mrs. Norwood. Yes, certainly. We will submit that to you.

[The following information was subsequently supplied for the record:]

U.S. Department of Labor

Commissioner for Bureau of Labor Statistics Washington, D.C. 20212

NOV · 2 1987

Honorable William Proxmire United States Senate Washington, D.C. 20510

Dear Senator Proxmire:

At a recent Joint Economic Committee Hearing on the Employment Situation, I told you about a summary of recent research on the economic effects of minimum wage laws. As requested, I am sending you a copy of that summary.

If I can be of any further assistance, please let me know.

Sincerely yours,

Quet

JANET L. NORWOOD Commissioner

Enclosure

Mrs. Norwood. The study summarized all the empirical work that we could find, and there is quite a bit of it. It is a rather substantial study.

As you know, the economics profession has generally taken the position that raising the minimum wage would reduce employment. Yet it is interesting that the empirical results are not entirely clear on that subject.

Most of the studies that have been done do show some disemployment effects on teenagers, but there is a great deal of uncertainty about the effect on adults.

The statistic that is most often quoted is a 1-percent reduction in youth employment in response to a 10-percent increase in the minimum wage. But the results, looking at blacks versus whites, women versus men, are quite mixed. There are those saying there is a big reduction in unemployment effect, and there are those who say the reverse.

Senator PROXMIRE. Let me just interrupt to say from a logical standpoint, a lot of people say well, of course you have less employment. If people have to pay more, they are not going to hire people to do the job.

On the other hand, if people who have these low incomes are paid a little more, this is high velocity spending, believe me. They don't put that in the bank. They spend it. It is a high turnover, and therefore it increases demand to a very considerable extent.

Mrs. Norwood. That is right. And there can also be an important productivity effect that would be important, I think, and would have an effect on lowering inflation.

Nevertheless, our review has shown that there are studies on both sides, and it is not easy to point to the literature and come up with a specific conclusion.

I would like to comment if I might, Senator, on one provision of the bill, at least the one that I have seen that is being considered, and that is the indexation aspect. So far as I understand it, the provision indexes the minimum wage to average hourly earnings.

There are some technical problems with the use of a single month's preliminary figure. Quite apart from that, it seems to me that one implication of that approach is that an increase in productivity in some industries that resulted in increased wages in those industries, would be transferred into the minimum wage industries.

It might be that given the obvious desire to improve social as well as economic conditions, that one might like to look at indexation using a price measure rather than the wage measure. I just throw that out to you. Senator PROXMIRE. Mrs. Norwood, thank you very, very much for excellent testimony, as always, and also Mr. Dalton and Mr. Plewes for your very substantial help and understanding the unemploy-ment situation and the inflation situation. As usual, you did a top-flight job. I will be back here many times

before I am through. Mrs. Norwood. I certainly hope so. Senator PROXMIRE. Well, like it not, I will be here. Thank you

very much.

The committee will stand adjourned.

[Whereupon, at 10:25 a.m., the committee adjourned, subject to the call of the Chair.]

EMPLOYMENT-UNEMPLOYMENT

FRIDAY, OCTOBER 2, 1987

CONGRESS OF THE UNITED STATES,

JOINT ECONOMIC COMMITTEE,

Washington, DC.

The committee met, pursuant to notice, at 9:30 a.m., in room SD-628, Dirksen Senate Office Building, Hon. Paul S. Sarbanes (chairman of the committee) presiding.

Present: Senator Sarbanes and Representatives Scheuer and Fish.

Also present: Judith Davison, executive director; and William Buechner and Dale Jahr, professional staff members.

OPENING STATEMENT OF SENATOR SARBANES, CHAIRMAN

Senator SARBANES. The committee will come to order.

We are pleased once again to have Commissioner Norwood, the Commissioner of the Bureau of Labor Statistics, to testify on the September labor market statistics.

This is the first of two hearings that the committee will be holding this morning and we will be following it with a hearing on air traffic safety.

Commissioner, also, we're voting over on the floor and I think we should get started. We'll just have to handle the situation as best we can if a rollcall begins.

Before you begin, Mrs. Norwood, Senator D'Amato has requested that his opening statement be placed in the record. He had another commitment and is unable to be present.

[The written opening statement of Senator D'Amato follows:]

(125)

83-467 0 - 88 - 5

WRITTEN OPENING STATEMENT OF SENATOR D'AMATO

GOOD MORNING, MR. CHAIRMAN. I WOULD ALSO LIKE TO WELCOME DR. JANET NORWOOD. COMMISIONER NORWOOD, I AM MOST INTERESTED IN YOUR OBSERVATIONS ON SEPTEMBER'S EMPLOYMENT FIGURES.

AS WE ALL KNOW, LAST MONTH YOU REPORTED TO THIS COMMITTEE EMPLOYMENT FIGURES FOR AUGUST THAT WERE AT THEIR LOWEST SINCE THE END OF 1979. YOU REPORTED THAT THE TOTAL CIVILIAN EMPLOYMENT STOOD AT 113,100,000, A NEW RECORD HIGH. AN IMPRESSIVE INCREASE OF 354,000 IN JUST ONE MONTH'S TIME. THE UNEMPLOYMENT RATE IN AUGUST REMAINED STABLE AT 6.0 PERCENT.

YOUR REPORT SHOWS CONTINUED STRENGTH IN OUR ECONOMY THROUGH EXPANSION AND CREATION OF NEW JOBS. THESE FIGURES EXCEEDED THE EXPECTATIONS OF MOST ECONOMIC FORECASTERS.

FOR THE MONTH OF SEPTEMBER, THE UNEMPLOYMENT RATE <u>DECREASED</u> BY 0.1 OF A PERCENT TO 5.9 PERCENT. THE NUMBER OF INDIVIDUALS EMPLOYED, AS SHOWN BY BUSINESS PAYROLLS, <u>INCREASED</u> BY APPROXIMATELY 130,000 TO 113,230,000. IN THE STATE OF NEW YORK, THE UNEMPLOYMENT RATE FOR THE MONTH OF SEPTEMBER REMAINED CONSTANT AT 4.5 PERCENT. OVERALL, DR. NORWOOD, THESE FIGURES PAINT A BRIGHT EMPLOYMENT PICTURE IN OUR NATION.

FOR THE PAST YEAR, THE EMPLOYMENT SITUATION IN THIS NATION HAS BEEN VERY STABLE. UNEMPLOYMENT REMAINS STEADY AROUND 6 PERCENT. EMPLOYMENT LEVELS ARE AT AN ALL TIME HIGH. THIS IS DUE IN NO SMALL PART TO THE LOWER INTEREST RATES AND LOWER INFLATION THAT HAVE RESULTED FROM THE PRESIDENT'S ECONOMIC PROGRAM. HOWEVER, THE LEVEL OF EMPLOYMENT NOT ONLY REFLECTS THE GENERAL HEALTH OF THE ECONOMY AND SPECIFIC INDUSTRIES, BUT ALSO THE INCREASE OR DECREASE IN THE NUMBER OF AMERICANS BRINGING HOME PAYCHECKS AND THEIR ABILITY TO MAKE PURCHASES. THEREFORE, WE MUST ALSO BE AWARE OF THE DROP IN THE VALUE OF THE DOLLAR AND ITS IMPACT ON THE AMERICAN WORKER. AMERICANS NEED BOTH JOBS AND GOOD SALARIES TO PROVIDE FOR THEMSELVES AND THEIR FAMILIES.

IT IS MY HOPE THAT YOUR TESTIMONY TODAY WILL PROVIDE ADDITIONAL ENCOURAGING EMPLOYMENT INFORMATION.

THANK YOU, MR. CHAIRMAN.

Senator SARBANES. Mrs. Norwood, why don't you go ahead and proceed.

STATEMENT OF HON. JANET L. NORWOOD, COMMISSIONER, BUREAU OF LABOR STATISTICS, DEPARTMENT OF LABOR, AC-COMPANIED BY KENNETH V. DALTON, ASSOCIATE COMMIS-SIONER, OFFICE OF PRICES AND LIVING CONDITIONS; AND JOHN E. BREGGER. ASSISTANT COMMISSIONER. OFFICE OF **CURRENT EMPLOYMENT ANALYSIS**

Mrs. Norwood. Thank you very much, Mr. Chairman. We are pleased to be here. I have with me Kenneth Dalton, our Associate Commissioner for Prices and Living Conditions; and John Bregger, on my left, our Assistant Commissioner for Current Employment Analysis.

Labor market signs were positive in September. Unemployment has been on a downward trend, and factory employment continued to grow. Both the overall jobless rate, at 5.8 percent, and the civilian worker rate, at 5.9 percent, have declined steadily during the year and in September were 1.1 percentage points below the levels of a year earlier.

In September, the household survey showed declines in both the labor force and employment. However, both had increased markedly in the previous month. Since April, the month before the large summer seasonal movements began, the labor force has increased by more than 500,000, and employment has grown by over 900,000. The civilian jobless rate dropped from 6.3 to 5.9 percent over the same 5-month period.

The business survey was up by 130,000 from August to September. Were it not for teachers and other school personnel off business payrolls because of strikes, payroll employment would have increased by about 200,000 over the month. Factory employment accounted for 55,000 of that gain. Indeed, manufacturing employment has increased by 165,000 in just the last 3 months. These gains have been widespread. The BLS diffusion index, which is heavily weighted toward manufacturing, reached a hefty 65 percent in September. It is true that factory hours were down over the month, but the decline merely reflects the unusual occurrence of the Labor Day holiday falling in the reference week of the survey.

In contrast to factory employment, construction jobs have lagged—they are down 35,000 over the month and 60,000 since this January. Employment in the mining industry has been growing slowly but steadily. Mining jobs have increased by about 40,000 since January, most of them in the oil and gas extraction industry.

In the service-producing sector, retail trade showed the only real strength in September, adding 70,000 jobs. The finance, insurance, and real estate industry, which has grown steadily during the current expansion, failed to post any employment increase, probably reflecting the joint effects of rising interest rates and construction activity slowdown. Employment in the services industry grew by 35,000, a very small gain for this industry.

The improvement in factory job performance over the last few months may have affected the relationship between the jobless rates of men and women. During the recession of the early 1980's,

the predominantly male factory work force was hard hit, and the unemployment rate for men moved upward, surpassing the rate for women. More recently, the situation has changed—the rate for adult men and women both were near 6 percent in December and 5.5 percent in April. But partly because of the growth in factory jobs over the last few months, the rate for adult men has fallen to 5 percent in September, while the rate for adult women, at 5.4 percent, has shown little further improvement.

The jobless rate for teenagers has been relatively sticky. There has been considerable anecdotal evidence of localized labor shortages and rising wages in some jobs traditionally held by young people. Even so, their unemployment rate, at 16.3 percent in September, has shown less improvement, relatively speaking, than the adult rates during 1987. However, the black teenage jobless rate, although still a very high 30 percent, has improved markedly in recent months. The black teenage employment-population ratio has also shown some improvement, but that measure still stands at 30 percent, compared to nearly 50 percent for white teenagers.

In September, the current expansion reached 58 months, matching the length of the one which began in the spring of 1975. Job growth has been vigorous in both expansions, but the current expansion reflects the restructuring of industry which accelerated during the 1980's. The number of factory jobs has grown much less than in the late 1970's. Employment in the oil and gas extraction industry rose by 50 percent in the comparable period after 1975 but declined by 33 percent over the current expansion.

In both periods, strong job growth occurred in the service-producing sector. But even here, some differences between the two expansions can be seen in the composition of that growth. During the current expansion, for example, one in every eight new jobs has been in business services, far more than in the period after 1975. Employment in communications and public utilities declined during the current period but rose after 1975. And State and local jobs have not grown as fast in the 1980 period as in the earlier one.

On the demographic side, the labor force has grown far more slowly in the current period as the number of teenagers entering the work force declined. Labor force participation of women continued to increase but at a slower rate in the 1980's than in the 1970's.

In summary, I believe that labor market developments remain encouraging. The improvement we have seen in unemployment held in September, and employment in the Nation's factories continued to grow.

Mr. Chairman, we would be glad to try to answer any questions you have.

Unemployment rates of all civilian workers by alternative seasonal adjustment methods

SOURCE: U.S. DEPARTMENT OF LABOR Bureau of Labor Statistics October 1987

٠

130

.

(1) Unadjusted rate. Unemployment rate for all civilian workers, not seasonally adjusted.

(2) Official procedure (X-11 ARIMA method). The published seasonally adjusted rate for all civilian workers. Each of the 3 major civilian labor force components-magricultural employment, nonagricultural employment and unemployment-for 4 age-sex groups-males and females, ages 16-19 and 20 years and over-are seasonally adjusted independently using data from January 1974 forward. The data series for each of these 12 components are extended by a year at each end of the original series using ARIMA (Auto-Regressive, Integrated, Moving Average) models chosen specifically for each series. Each extended series is then seasonally adjusted with the X-11 portion of the X-11 ARIMA program. The 4 teenage unemployment model, while the other components are adjusted with the additive adjustment model, while the other components are adjusted with the additive adjustment model, while the other components are adjusted with the multiplicative model. The unemployment rate is computed by summing the 4 seasonally adjusted unemployment components and calculating that total as a percent of the civilian labor force total derived by summing all 12 seasonally adjusted components. All the seasonally adjusted series are revised at the end of each year: Extrapolated factors for January-June are computed at the beginning of each year; extrapolated factors for July-December are computed in the middle of the year after the June data become available. Each set of 6-month factors are published in advance, in the January and July issues, respectively, of <u>Employment and Earnings</u>.

(3) Concurrent (as first computed, X-11 ARIMA method). The official procedure for computation of the rate for all civilian workers using the 12 components is followed except that extrapolated factors are not used at all. Each component is seasonally adjusted with the X-11 ARIMA program each month as the most recent data become available. Rates for each month of the current year are shown as first computed; they are revised only once each year, at the end of the year when data for the full year become available. For example, the rate for January 1974 through January 1984.

(4) <u>Concurrent (revised, X-11 ARIMA method)</u>. The procedure used is identical to (3) above, and the rate for the current month (the last month displayed) will always be the same in the two columns. However, all previous months are subject to revision each month based on the seasonal adjustment of all the components with data through the current month.

(5) <u>Stable (X-11 ARIMA method</u>). Each of the 12 civilian labor force components is extended using ARIMA models as in the official procedure and then run through the X-11 part of the program using the stable option. This option assumes that seasonal patterns are basically constant from year-to-year and computes final seasonal factors as unweighted averages of all the seasonal-irregular components for each month across the entire span of the period adjusted. As in the official procedure, factors are extrapolated in 6-month intervals and the series are revised at the end of each year. The procedure for computation of the rate from the seasonally adjusted components is also identical to the official procedure.

(6) <u>Total (X-11 ARIMA method)</u>. This is one alternative aggregation procedure, in which total unemployment and civilian labor force levels are extended with ARIMA models and directly adjusted with multiplicative adjustment models in the X-11 part of the program. The rate is computed by taking seasonally adjusted total unemployment as a percent of seasonally adjusted total civilian labor force. Factors are extrapolated in 6-month intervals and the eries revised at the end of each year.

(7) <u>Residual (X-11 ARIMA method)</u>. This is another alternative aggregation method, in which total civilian employment and civilian labor force levels are extended using ARIMA models and then directly adjusted with multiplicative adjustment models. The seasonally adjusted unemployment level is derived by subtracting seasonally adjusted employment from seasonally adjusted labor force. The rate is then computed by taking the derived unemployment level as a percent of the labor force level. Factors are extrapolated in 6-month intervals and the series revised at the end of each year.

(8) <u>12-month extrapolation (X-11 ARIMA method</u>). This approach is the same as the official procedure except that the factors are extrapolated in 12-month intervals. The factors for January-December of the current year are computed at the beginning of the year based on data through the preceding year. The values for January through June of the current year are the same as the official values since they reflect the same factors.

(9) X-11 method (official method before 1980). The method for computation of the official procedure is used except that the series are not extended with ARIMA models and the factors are projected in 12-month intervals. The standard X-11 program is used to perform the seasonal adjustment.

<u>Methods of Adjustment</u>: The X-11 ARIMA method was developed at Statistics Canada by the Seasonal Adjustment and Times Series Staff under the direction of Estela Bee Dagum. The method is described in <u>The X-11 ARIMA Seasonal Adjustment Method</u>, by Estela Bee Dagum, Statistics Canada Catalogue No. 12-564E, February 1980.

The standard X-11 method is described in X-11 Variant of the Census Method II Seasonal Adjustment Program, by Julius Shiskin, Allan Young and John Musgrave (Technical Paper No. 15, Bureau of the Census, 1967).

Washington, D.C. 20212

Technical information: (202) 523-1371 523-1944 523-1959 Media contact: 523-1913

TRANSMISSION OF MATERIAL IN THIS RELEASE IS EMBARGOED UNTIL 8:30 A.M. (EDT), FRIDAY, OCTOBER 2, 1987

THE EMPLOYMENT SITUATION: SEPTEMBER 1987

Unemployment was little changed in September, the Bureau of Labor Statistics of the U.S. Department of Labor reported today. The overall unemployment rate was 5.8 percent, and the rate for civilian workers was 5.9 percent. Both rates were 1.1 percentage points lower than a year earlier, with the improvement having been particularly strong since February.

The number of nonagricultural payroll jobs--as measured by the monthly survey of business establishments--edged up about 130,000, after seasonal adjustment. Total civilian employment--as measured by the monthly survey of households--declined by 310,000, following an increase of a similar magnitude in August. Over the past year, employment levels in the establishment and household series have advanced by 2.4 and 2.8 million, respectively.

Unemployment (Household Survey Data)

Both the number of unemployed persons in September--7.1 million--and the civilian worker unemployment rate--5.9 percent--were little changed from August, after seasonal adjustment. Similarly, jobless rates for adult men (5.0 percent), adult women (5.4 percent), teenagers (16.3 percent), whites (5.1 percent), blacks (12.3 percent), and Hispanics (8.2 percent) showed little or no over-the-month change. (See tables A-2 and A-3.)

The mean duration of unemployment, at 14.2 weeks, was also little changed in September, while median duration declined to 5.7 weeks. In recent months, both measures have edged down below levels posted earlier this year. (See table A-7.)

Civilian Employment and the Labor Force (Household Survey Data)

Total civilian employment declined more than usual in September and, after adjustment for seasonality, was down 310,000 to 112.8 million, offsetting an increase of similar magnitude in August. The August increase and September decline can be largely traced to the pattern of youth employment this summer. Teenage employment normally declines markedly (before seasonal adjustment) during the months of August and especially September, as young workers leave summer jobs in preparation for their return to school. This year, however, an unusually large group of

teenagers remained in their jobs through the August reference week. This resulted in the unusually large seasonally adjusted increase in youth employment in August and the decline of similar magnitude in September.

Reflecting these developments, the percentage of the total civilian population that is employed--the employment-population ratio--receded to 61.6 percent in September, the same as in July. (See table A-2.)

After seasonal adjustment, the civilian labor force declined by 440,000 in September to 119.9 million; this drop also was confined largely to teenagers. With this decline, the labor force participation rate fell to 65.4 percent, still high by historical standards. The labor force has grown by 1.6 million over the past year:

Discouraged Workers (Household Survey Data)

At 1.0 willion in the third quarter, the number of discouraged workers--persons who report that they want to work but are not looking for jobs because they believe they cannot find any--was little changed from the level for the second quarter. Blacks and women continue to be disproportionately represented among the discouraged. (See table A-14.)

Industry Payroll Employment (Establishment Survey Data)

The number of nonagricultural payroll jobs edged up 130,000 in September to 102.4 million, seasonally adjusted. The figures were dampened by the absence from payrolls of about 65,000 teachers and support workers due to labor disputes. (See table B-1.)

Manufacturing employment rose by 55,000 in September to 19.2 million, seasonally adjusted, as growth was widespread in both the durable and nondurable goods components. Job gains were particularly notable' in primary metals and machinery. Factory employment increases have totaled 165,000 since June, raising the employment level to its highest point since August 1985.

Elsewhere in the goods sector, employment in mining continued its gradual recovery. Growth in the industry has totaled 40,000 since its January low, mostly in its oil and gas extraction component. In contrast, construction employment declined by 35,000 in September and was down by 60,000 so far this year.

In the service-producing sector, enployment growth was generally moderate in September. Job gains were unusually slow in the services industry, which increased by 35,000, compared with an average increase of close to 90,000 over the current expansion. There was no increase at all in finance, insurance, and real estate; wholesale trade; and government, where employment was held down by teacher strikes. In contrast, retail trade employment increased by 70,000, more than offsetting the small decline of the previous month.

Weekly Hours (Establishment Survey Data)

The average workweek of production or nonsupervisory workers on private nonagricultural payrolls was down 0.3 hour to 34.6 hours, seasonally adjusted. The manufacturing workweek dropped by 0.6 hour to 40.4, and factory overtime fell by 0.2 hour to 3.6 hours. These declines reflected the unusual occurrence of Labor Day in the survey period, as some employees were not paid for the holiday and others worked fewer overtime hours. As a result of the decline in the average workweek, the index of aggregate weekly hours of production on nonsupervisory workers on private nonagricultural payrolls dropped by 0.8 percent to 120.2 (1977=100), seasonally adjusted. (See table B-5.).

Hourly and Weekly Earnings (Establishment Survey Data)

Average hourly earnings were unchanged in September, while average weekly earnings fell by 0.9 percent, seasonally adjusted, also reflecting the decline in the workweek. Prior to seasonal adjustment, hourly earnings increased by 12 cents to \$9.06, and weekly earnings were down \$1.20 to \$314.38. (See table B-3.)

The Hourly Earnings Index (Establishment Survey Data)

The Hourly Earnings Index (HEI) was 174.7 (1977=100) in September, seasonally adjusted, an increase of 0.3 percent from August. For the 12 months ended in September, the increase was 2.9 percent. The HEI excludes the effects of two types of changes unrelated to underlying wage rate movements--fluctuations in manufacturing overtime and interindustry employment shifts. In dollars of constant purchasing power, the HEI decreased 1.6 percent during the 12-month period ended in August. (See table B-4.)

The Employment Situation for October 1987 will be released on Friday, . November 6, at 8:30 A.M. (EST).

Explanatory Note

This news release presents statistics from two major surveys, the Current Population Survey (household survey) and the Current Employment Statistics Survey (establishment survey). The household survey provides the information on the labor force, total employment, and unemployment that appears in the A tables, marked HOUSEHOLD DATA. It is a sample survey of about 59.500 households that is conducted by the Bureau of the Census with most of the findings analyzed and published by the Bureau of Labor Statistics (BLS).

The establishment survey provides the information on the employment, hours, and earnings of workers on nonagricultural payrolls that appears in the B tables, marked ESTABLISHMENT DATA. This information is collected from payroll records by BLS in cooperation with State agencies. The sample includes over 290,000 establishments employing over 38 million people.

For both surveys, the data for a given month are actually collected for and relate to a particular week. In the household survey, unless otherwise indicated, it is the calendar week that contains the 12th day of the month, which is called the survey week. In the establishment survey, the reference week is the pay period including the 12th, which may or may not correspond directly to the calendar week.

The data in this release are affected by a number of technical factors, including definitions, survey differences, seasonal adjustments, and the inevitable variance in results between a survey of a sample and a census of the entire population. Each of these factors is explained below.

Coverage, definitions, and differences between surveys

The sample households in the household survey are selected so as to reflect the entire civilian noninstitutional population 16 years of age and older. Each person in a household is classified as employed, unemployed, or not in the labor force. Those who hold more than one job are classified according to the job at which they worked the most hours.

People are classified as *employed* if they did any work at all as paid civilians; worked in their own business or profession or on their own farm; or worked 15 hours or more in an enterprise operated by a member of their family, whether they were paid or not. People are also counted as employed if they were on unpaid leave because of illness, bad weather, disputes between labor and management, or personal reasons. Members of the Armed Forces stationed in the United States are also included in the employed total.

People are classified as unemployed, regardless of their eligibility for unemployment benefits or public assistance, if they meet all of the following criteria: They had no employment during the survey week; they were available for work at that time; and they made specific efforts to find employment sometime during the prior 4 weeks. Persons laid off from their former jobs and awaiting recall and those expecting to report to a job within 30 days need not be looking for work to be counted as unemployed.

The labor force equals the sum of the number employed and the number unemployed. The unemployment rate is the percentage of unemployed people in the labor force (civilian plus the resident Armed Forces). Table A-5 presents a special grouping of seven measures of unemployment based on varying definitions of unemployment and the labor force. The definitions are provided in the table. The most restrictive definition yields U-1 and the most comprehensive yields U-7. The overall unemployment rate is U-Sa, while U-5b represents the same measure with a civilian labor force base.

Unlike the household survey, the establishment survey only counts wage and salary employees whose names appear on the payroll records of nonagricultural firms. As a result, there are many differences between the two surveys, among which are the following:

— The household survey, although based on a smaller sample, reflects a larger segment of the population; the establishment survey excludes agriculture, the self-employed, unpaid family workers, private household workers, and members of the resident Armed Forces;

- The household survey includes people on unpaid leave among the employed; the establishment survey does not;

- The household survey is limited to those 16 years of age and older; the establishment survey is not limited by age;

 The household survey has no duplication of individuals, because each individual is counted only once; in the establishment survey, employees working at more than one job or otherwise appearing on more than one payroll would be counted separately for each appearance.

Other differences between the two surveys are described in "Comparing Employment Estimates from Household and Payroll Surveys," which may be obtained from the BLS upon request.

Seasonal adjustment

Over the course of a year, the size of the Nation's labor force and the levels of employment and unemployment undergo sharp fluctuations due to such seasonal events as changes in weather, reduced or expanded production, harvests, major holidays, and the opening and closing of schools. For example, the labor force increases by a large number each June, when schools close and many young people enter the job market. The effect of such seasonal variation can be very large; over the course of a year, for example, seasonality may account for as much as 95 precent of the month-to-month changes in unemployment.

Because these seasonal events follow a more or less regular pattern each year, their influence on statistical trends can be eliminated by adjusting the statistics-from-month to month. These adjustments make nonseasonal developments, such as declines in economic activity or increases in the participation of women in the labor force, easier to spot. To return to the school's-out example, the large number of people entering the labor force each June is likely to obscure any other changes that have taken place since May, making it difficult to determine if the level of economic activity has risen or declined. However, because the effect of students finishing school in previous years is known, the statistics for the current year can be adjusted to allow for a comparable change. Insofar as the seasonal adjustment is made correctly, the adjusted figure provides a more useful tool with which to analyze changes in economic activity.

Measures of labor force, employment, and unemployment contain components such as age and sex. Statistics for all employees, production workers, average weekly hours, and average hourly earnings include components based on the employer's industry. All these statistics can be seasonally adjusted either by adjusting the total or by adjusting each of the components and combining them. The second procedure usually yields more accurate information and is therefore followed by BIS. For example, the seasonally adjusted figure for the labor force is the sum of eight seasonally adjusted civilian employment components, plus the resident Armed Forces total (not adjusted for seasonality), and four seasonally adjusted unemployment components; the total for unemployment is the sum of the four unemployment components; and the overall unemployment rate is derived by dividing the resulting estimate of total unemployment by the estimate of the labor force.

The numerical factors used to make the seasonal adjustments are recalculated regularly. For the household survey, the factors are calculated for the January-June period and again for the July-December period. The January revision is applied to data that have been published over the previous 5 years. For the establishment survey, updated factors for seasonal adjustment are calculated only once a year, along with the introduction of new benchmarks which are discussed at the end of the next section.

Sampling variability

Statistics based on the household and establishment surveys are subject to sampling error, that is, the estimate of the number of people employed and the other estimates drawn from these surveys probably differ from the figures that would be obtained from a complete census, even if the same questionnaires and procedures were used. In the household survey, the amount of the differences can be expressed in terms of standard errors. The numerical value of a standard error depends upon the size of the sample, the results of the survey, and other factors. However, the numerical value is always such that the chances are approximately 68 out of 100 that an estimate based on the samble will differ by no more than the standard error from the results of a complete census. The chances are approximately 90 out of 100 that an estimate based on the sample will differ by no more than 1.6 times the standard error from the results of a complete census. At approximately the 90-percent level of confidence—the confidence limits used by BLS in its analyses—the error for the monthly change in total employment is on the order of plus or minus 328,000; for total unemployment it is 220,000; and, for the overall unemployment rate, it is 0.19 percentage point. These figures do not mean that the sample results are off by these magnitudes but, rather, that the chances are approximately 90 out of 100 that the "true" level or rate would not be expected to differ from the estimates by more than these amounts.

Sampling errors for monthly surveys are reduced when the data are cumulated for several months, such as quarterly or annually. Also, as a general rule, the smaller the estimate, the larger the sampling error. Therefore, relatively speaking, the estimate of the size of the labor force is subject to less error than is the estimate of the number unemployed. And, among the unemployed, the sampling error for the jobless rate of adult men, for example, is much smaller than is the error for the jobless rate of teenagers. Specifically, the error on monthly change in the jobless rate for men is .26 percentage point; for teenagers, it is 1.25 percentage points.

In the establishment survey, estimates for the 2 most current months are based on incomplete returns; for this reason, these estimates are labeled preliminary in the tables. When all the returns in the sample have been received, the estimates are revised. In other words, data for the month of September are published in preliminary form in October and November and in final form in December. To remove errors that build up over time, a comprehensive count of the employed is conducted each year. The results of this survey are used to establish new benchmarks—comprehensive counts of employment—against which month-to-month changes can be measured. The new benchmarks also incorporate changes in the classification of industries and allow for the formation of new establishments.

Additional statistics and other information

In order to provide a broad view of the Nation's employment situation, BIS regularly publishes a wide variety of data in this news release. More comprehensive statistics are contained in *Employment and Earnings*, published each month by BIS. It is available for \$8.50 per issue or \$22.00 per year from the U.S. Government Printing Office, Washington, D.C.; 20204. A check or money order made out to the Superintendent of Documents must accompany all orders.

Employment and Earnings also provides approximations of the standard errors for the household survey data published in this release. For unemployment and other labor force categories, the standard errors appear in tables B through J of its "Explanatory Notes." Measures of the reliability of the data drawn from the establishment survey and the actual amounts of revision due to benchmark adjustments are provided in tables M. O, P, and Q of that publication. ¹Data relate to production workers in mining and manufacturing; to construction workers in construction; and to nonsupervisory workers in transportation and public utilities, non-least and reall track (innore, insurance, and reservises); These process account for approximately four-filths of the total employees on private nonsprovingel pupylis.

⁴ This series is not published seasonally adjusted since the seasonal component is small relative to the trand-cycle and/or irregular components and consequently cannot be separated with sufficient precision. p a preliminary.

minery.

Senator SARBANES. Well, Commissioner, thank you very much. I'll be very brief since there is a vote going on.

The civilian labor force over the course of this year has been growing, as I understand it, at about half the rate of the previous 4 years, about 100,000 a month.

What's the explanation for this? You make reference right at the close of your statement to this when you say——

Mrs. Norwood. Yes.

Senator SARBANES [continuing]. The number of teenagers. Reflecting birth rates of 16 to 18 years ago? Is that what we're experiencing?

Mrs. NORWOOD. Yes. That's right. There are fewer teenagers in the population and there are even fewer of them coming into the labor force. As a result, there is less really upward pressure on the unemployment rate since teenagers always have much higher unemployment rates than the rest of the population.

Senator SARBANES. And what does that demographic line look like for the next 3 to 5 years?

Mrs. NORWOOD. We anticipate that from now through the turn in the century the labor force will be growing at only about one-half the rate that it has grown in the past. This is largely because until about the middle of the 1990's teenagers will continue to come in very slowly. Then that will turn around a bit. Overall, the labor force will age. The average age of the labor force will be much higher in the future than it has been in recent years.

Senator SARBANES. You made reference to the improvement in the black teenage jobless rate. What do you perceive to be the explanation?

Mrs. NORWOOD. We have seen an increase in the labor force participation of blacks in general, particularly the teenagers, and more of them have obtained jobs. Nevertheless, their rates, though they are not 45 percent as they were a while ago, are still 30 percent.

Senator SARBANES. Is your perception that their situation has improved simply because of the overall tightening of the labor market, or is there something else at work?

Mrs. Norwood. Well, it may be the overall effect of the economy. As more and more people go back to work, then the jobs come to those who have the hardest time in the labor market. It's probably that more than anything else. They do better when there are more jobs and our employment growth has been considerable. There's still a long way to go.

Senator SARBANES. Well, I'm not going to be able, as those buzzers indicate, to spend any more time with you. I regret that. We thank you very much for being with us again. We look forward to seeing you again next month.

The hearing is adjourned.

[Whereupon, at 9:40 a.m., the committee adjourned, subject to the call of the Chair.]
