## JOINT ECONOMIC COMMITTEE

(Created pursuant to sec. 5(a) of Public Law 304, 79th Cong.)

RICHARD BOLLING, Missouri, *Chairman*

HUBERT H. HUMPHREY, Minnesota, *Vice Chairman*

### HOUSE OF REPRESENTATIVES

HENRY S. REUSS, Wisconsin  
WILLIAM S. MOORHEAD, Pennsylvania  
LEE H. HAMILTON, Indiana  
GILLIS W. LONG, Louisiana  
OTIS G. PIKE, New York  
CLARENCE J. BROWN, Ohio  
GARRY BROWN, Michigan  
MARGARET M. HECKLER, Massachusetts  
JOHN H. ROUSSELOT, California

### SENATE

JOHN SPARKMAN, Alabama  
WILLIAM PROXMIRE, Wisconsin  
ABRAHAM RIBICOFF, Connecticut  
LLOYD BENTSEN, Texas  
EDWARD M. KENNEDY, Massachusetts  
JACOB K. JAVITS, New York  
WILLIAM V. ROTH, Jr., Delaware  
JAMES A. McCCLURE, Idaho  
ORRIN G. HATCH, Utah

JOHN R. STARK, *Executive Director*

LOUIS C. KRAUTHOFF II, *Assistant Director*

RICHARD F. KAUFMAN, *General Counsel*

### ECONOMISTS

G. THOMAS CATOR  
WILLIAM A. COX  
THOMAS F. DERNBURG  
ROBERT D. HAMRIN

KENT H. HUGHES  
SARAH JACKSON  
JOHN R. KARLIK  
L. DOUGLAS LEE

PHILIP McMARTIN  
DEBORAH NORELLI  
GEORGE R. TYLER

### MINORITY

CHARLES H. BRADFORD  
M. CATHERINE MILLER

STEPHEN J. ENTIN

GEORGE D. KRUMBHAAR, Jr.  
MARK R. POLICINSKI

## LETTERS OF TRANSMITTAL

---

AUGUST 22, 1977.

*To the Members of the Joint Economic Committee:*

Transmitted herewith for use by the Joint Economic Committee, the Congress, and the interested public is a factual and interpretative assessment of the policy and performance of the East European economies at home and abroad entitled "East European Economies Post-Helsinki." This compilation of invited papers is designed to meet the interests of the committee and the Congress by providing an up-to-date body of data and interpretative comment on the domestic and foreign economic relations of the countries of Eastern Europe, primarily Bulgaria, Romania, Hungary, Czechoslovakia, Poland, the German Democratic Republic (G.D.R.), Albania, and Yugoslavia.

It is hoped, that this volume, drawing on research of North American, Israeli, and European academic specialists as well as professionals in the U.S. Government will serve as an aid and a stimulus to scholarship on this subject area. The committee is deeply indebted to the scholars who gave so generously of their time and expertise. They are listed in the executive director's memorandum to me, and I would like to express on behalf of the committee our gratitude for their invaluable efforts.

Finally, we wish to take this opportunity to express our gratitude to the Congressional Research Service for making available the services of John P. Hardt, who helped plan the scope of the research and coordinated and edited the contributions for the present study.

It should be understood that the views contained in this study are not necessarily those of the Joint Economic Committee nor of individual members.

Sincerely,

RICHARD BOLLING,  
*Chairman, Joint Economic Committee.*

---

AUGUST 17, 1977.

HON. RICHARD BOLLING,  
*Chairman, Joint Economic Committee,  
U.S. Congress, Washington, D.C.*

DEAR MR. CHAIRMAN: Transmitted herewith is a volume of materials on the economies of Eastern Europe entitled "East European Economies Post-Helsinki." The study contains papers written by scholars and specialists who, as recognized authorities on Eastern Europe, were invited to contribute. The specialists in question have been drawn from the ranks of various universities here and abroad, private research institutes, several departments of the Federal Government, and the Library of Congress. The papers they have submitted,

in response to our request, cover the broad range of topics dealing with the recent performance of East European economies. Included among these topics are economic policy, the defense burden, agriculture, industry, population, manpower, education, technology, chemical and petroleum automotive transport and energy industries, commercial relations, balance of payments, and industrial cooperation.

This volume has a new and unique section on the individual countries of Eastern Europe. We are especially indebted to Prof. Paul Marer in arranging that section and organizing a seminar in February in Washington to assess the drafts. Numerous others contributed to this section and other sections in the volume. Special thanks are due to Prof. L. Dellins, Dr. Lawrence Brainard, Prof. Alan Brown, and Mr. Leo Tansky.

The Joint Economic Committee released predecessor volumes to this entitled, "Economic Developments in Countries of Eastern Europe," in 1969, and "Reorientation and Commercial Relations of the Economies of East Europe" in 1974. The committee has in recent years followed a pattern of periodic assessments of the economies of socialist states and has completed the following studies: "People's Republic of China: An Economic Assessment" in 1972, "Soviet Economic Prospects for the Seventies" in 1973, "China: An Economic Reassessment" in 1975, and "Soviet Economy in a New Perspective" in 1976.

The contributors to the study have been most considerate of our needs and generous in giving of their time and expertise to provide not only basic information but also an essential analytical perspective. The individual scholars who have participated in the preparation of the present study are:

Mark Allen  
Thad P. Alton  
Godfrey Baldwin  
Elizabeth M. Bass  
Max Baumer  
Morris Bornstein  
Josef C. Brada  
Jay A. Burgess  
Imogene Edwards  
Zbigniew M. Fallenbuchl  
Steven Flanders  
Robert Fraser  
John Haberstroh  
Donald J. Hasfurth  
Edward Hewett  
Vaclav Holesovsky  
Marvin R. Jackson  
Everett Jacobs  
Hans-Dieter Jacobsen  
Michael Kaser  
Michael Keren  
Martin J. Kohn  
Hedija H. Kravalis  
Nicholas R. Lang  
Gregor Lazarcik  
Allen J. Lenz  
Friedrich Levcik  
Susanne Lotarski

Paul Marer  
Jenelle Matheson  
Ivan Matusek  
Paul McCarthy  
Carl H. McMillan  
J. M. Montias  
John H. Moore  
Kathryn Melson  
Egon Neuberger  
Z. Edward O'Relley  
Richard Portes  
Helen Raffel  
Marc Rubin  
Adi Schnytzer  
Marjory E. Searing  
Arthur J. Smith  
Edwin M. Snell  
Vladimir Socor  
Karen C. Taylor  
Robert Teal  
Gary R. Teske  
Laura D'Andrea Tyson  
Pompiliu Verzariu, Jr.  
Edward T. Wilson  
Thomas A. Wolf  
Wassyl Znayenko  
Joan Parpart Zoeter

In addition, the committee received the wholehearted cooperation from the following private organizations and Government agencies:

Arizona State University  
 Birbeck College, University of London, England  
 Bureau of East-West Trade, Department of Commerce  
 Bureau of Intelligence and Research U.S. Department of State  
 University of California  
 Institute of Soviet and East European Studies, Carlton University, Canada  
 Office of Economic Research, Central Intelligence Agency  
 U.S. Chamber of Commerce  
 Institute on East Central Europe, Columbia University  
 Foreign Demographic Analysis Division, Department of Commerce  
 Department of Business and Economics, North Dakota State University  
 Hebrew University, Jerusalem, Israel  
 School of Business, Indiana University  
 L. W. International  
 University of Massachusetts  
 Law and Economics Center, University of Miami  
 University of Michigan  
 Graduate School of Business Administration, New York University  
 State University of New York at Stony Brook  
 Board of the Faculty of Social Studies, University of Oxford, England  
 Princeton University  
 Department of Economic and Social History, University of Sheffield, England  
 Stiftung Wissenschaft und Politik, Federal Republic of Germany  
 University of Texas  
 Office of the Assistant Secretary for International Affairs, Department of Treasury  
 Vienna Institute of Comparative Economics, Austria  
 University of Windsor, Canada  
 Institution for Social and Policy Studies, Yale University

It should be clearly understood that the views expressed in those papers are those of the individual contributors and do not necessarily represent the position of their respective governments, or private institutions, the Joint Economic Committee, individual members thereof, or the committee staff.

The Library of Congress made available the services of John P. Hardt, senior specialist in the Congressional Research Service, who bore major responsibility for planning the scope of the research, and coordinating and editing the contribution. He also wrote the summary for the present study. Dr. Hardt was assisted by Ronda Bresnick also of the Library staff.

Edward J. Jacobs provided valuable printing and editorial assistance.

JOHN R. STARK,  
*Executive Director, Joint Economic Committee.*

## SUMMARY

BY JOHN P. HARDT

Economic interdependence was recognized as a growing global need by the 35 signatory nations of the European Commission on Security and Cooperation in Helsinki in August 1975. The draft Brezhnev Constitution unveiled in June 1977 stressed the need for economic interdependence among the nations of the Council for Mutual Economic Cooperation (CMEA)<sup>1</sup> in Eastern Europe. Interest in the Soviet Union and Eastern Europe in East-West commercial relations is unabated. Indeed, fulfillment of CMEA national goals of modernization and improved living standards seem increasingly tied to economic relations with the Western industrial nations. Eastern Europe and the Soviet Union remain for the West one of the larger untapped markets for their expanding economies. As a result of this reciprocal interest in economic interdependence, "Basket Two" of the Helsinki Final Act, "Cooperation in the Field of Economics, of Science and Technology and the Environment," remains the least controversial and possibly most productive area for the Fall, 1977, agenda in the Belgrade follow up meeting to Helsinki. In spite of the views of some of the smaller nations of Europe security matters (Basket One) and human rights considerations (Basket Three) may be dominated by the Soviet-United States bilateral discussions.

Recent economic performance in the nations of Eastern Europe, including Yugoslavia and Albania, may be assessed by international standards of comparison as ranging from good to excellent. It would be ironic to stop on that note as leaders and populace, alike, generally view economic performance as insufficient to meet major policy needs or inadequate to fill strongly felt popular needs, e.g., 6 percent annual growth in GNP is not sufficient or adequate if a minimum of 7 percent is planned and required. Indeed it is no exaggeration to say that the tenure and effectiveness in the office of several of the Eastern party leaders depends, uniquely, on the performance of their economies. Circumscribed as the power of East European leadership is in security, political, and ideological matters economic policy remains the area of greatest indigenous autonomy.

Although the Soviets may have less control over economic issues than over other developments, the policies of the Eastern giant have a profound effect on the East European economies. Eastern Europe's economic dependence on the USSR has been recently underlined as the Soviets adjusted their energy export policy by raising oil prices to Eastern Europe quickly and steeply, and tightening their allocations. This onerous materials price burden added to the ever present defense

<sup>1</sup> CMEA, or the Council of Mutual Economic Assistance, is also abbreviated COMECON or CEMA in various papers of this compendium.

claims, makes the influence of Soviet policy on East Europe appear generally unfavorable. Offsetting this burden, the Soviet Union is still accepting East European goods in trade that can not be easily marketed elsewhere, especially in the West.

Unfavorable as Western inflation, credit and trade restrictions and recession have been for the critical development of East-West interdependence, the industrial West still appears to be the major source of good news. Western imports, technology, and supplies bear promise for necessary Eastern economic modernization and consumer improvement. Small as Western trade may be it often appears to represent the critical margin for economic success.

In 1969 the Joint Economic committee released its first volume on Eastern Europe, "Economic Developments in Countries of Eastern Europe." In 1974 "Reorientation and Commercial Relations of the Economies of Eastern Europe" was released by the committee. These volumes joined the triannual series that deals, in turn, with the economies of the Soviet Union, Eastern Europe and the Peoples Republic of China.

In the 34 chapters in this compendium, some 62 specialists from governmental and academic institutions in the United States, Federal Republic of Germany, United Kingdom, Israel, and Canada have assessed East European economic policy, performance, and prospects for the future. Special attention is given to changes in East European priorities and economic institutions, especially as they relate to commercial relations with the West. While the countries of CMEA or COMECON provide the central focus of the compendium, attention is also given to Albania, and Yugoslavia—not full members of CMEA. The German Democratic Republic (G.D.R.),<sup>2</sup> Poland, Czechoslovakia, Hungary, Romania, and Bulgaria form the core nations of CMEA. The U.S.S.R. is dealt with only to complete a frame of reference for analyzing policy and performance.

The chapters have been divided into three sections: Policy and Planning, Individual Country Studies, and Foreign Economic Relations. The second section on individual countries is a unique addition to the format of the earlier volumes. A special effort was made to solicit comparable assessments on the recent economic performances of the domestic and foreign economic relations of the CMEA East European Countries, Yugoslavia and Albania.

The authors have provided their own summaries and the reader may wish to make up his or her own mind on differences of professional viewpoints. The following are some of the major questions raised by the papers with an indication of answers and where in the volume the appropriate analysis may be found.

*1. How does economic performance rate as a policy issue in the eyes of East Europe leadership and populace? What are the major internal and external factors that influence East European economic performance? Is Eastern European performance of importance to global politics?*

The latent instability always present in Eastern Europe recently surfaced once again affecting most countries of the area. Rooted in the long suppression of civil rights, national aspirations and values and complicated economic grievances, the challenge posed by dissidents to those in power has startled local authorities,

<sup>2</sup> The German Democratic Republic is called East Germany by some authors.

alarmed their Soviet overlords, and raised new doubts among Western observers about the long-term ability of the existing Communist regimes to govern their populations. The question is not so much whether existing leaderships would be toppled—although in some countries this possibility cannot be altogether ruled out—but rather whether the system can adjust to cope with such pressures. Is it willing and/or able to react in an enlightened fashion, or will it regress into positions reminiscent of policies prevailing during the “cold war” days: Severe repressions at home and bitter hostility towards the West in foreign relations? In effect, will it jettison detente?

The dissent which currently plagues Eastern Europe has made the authorities there realize that a new crisis of confidence in the East-West relationship appears to have arisen that could well come to a head at the forthcoming review conference in Belgrade. In approaching that conference the East European regimes face a dilemma. On the one hand, they desire to maximize their access to Western technology, Western credits and markets to promote their economic progress. In this context the maintenance of Western goodwill is a necessity. On the other hand, the dissident demands for a more relaxed, liberal rule at home is perceived as a threat to the system and a demand to relinquish tested methods of rule—at least in the more orthodox countries. The failure to grant at least some of these demands, however, courts an adverse reaction in the West, could upset state-to-state relations with Western countries, and ultimately repel Western economic partners. The reaction to this dilemma is likely to be a major test of the East European regimes’ aptitude to govern. The outcome is by no means certain, except that the economic advantages would in all likelihood be secondary should there occur a real threat to the survival of the existing system. In addition, Soviet attitudes are likely to influence strongly all countries excepting such traditional mavericks as Yugoslavia, Albania, and Romania. (Matusek, pp. 3 and 11.)

Since 1960 the East European countries, like the U.S.S.R., have been engaged in “peaceful economic competition with the capitalist world.” They have kept their economies growing at least as fast as similar Western economies—much faster, according to their claims—without fundamental changes in institutions and policies. This feat has been accomplished at the cost of serious imbalances in their economies—consumer expectations that cannot be met, large inventories of hoarded materials and unsold goods, and import requirements that outrun export capabilities. They cannot go on in this way very much longer without outside help; the foreign trade deficits have become too large. And without refinancing of debts to the West, these are likely to become unmanageable in a few years, forcing a slowdown in economic growth. (Snell, p. 13.)

As argued in a previous paper, international inflation may be expected to have three important potential effects:

- (1) A tendency to reverse the liberalizing and decentralizing economic reform measures by moving toward greater degrees of centralization and greater use of administrative measures in the attempt to contain the impact.
- (2) A tendency to reduce the participation in the international division of labor and to try to return toward a policy of import substitution, and
- (3) A tendency toward a shift in trading patterns away from the West and toward CMEA where prices have been held more stable by a pricing policy which sets CMEA prices as equal to the average of several past years’ prices in world markets, thereby introducing significant lags into price increases (CMEA markets act as absorbers of price inflation). (Fallenbuchl, Neuberger, and Tyson, pp. 100–101.)

## 2. *What is the balance of benefits and costs that Soviet economic relations bring to the performance of the East European economies?*

Eastern Europe, the region where both World Wars and the Cold War originated, occupies a critical position in the European and world balance of power. The course of international politics since the second world war tends to confer added validity to the axiom whose best known expression was given by Halford Mackinder, projecting imperial control over Eastern Europe as the first and indispensable (although not in itself sufficient) precondition for the attainment of world hegemony: “Who rules Eastern Europe commands the Heartland; who rules the Heartland commands the World-Island; who rules the World-Island commands the World.” The establishment and perpetuation of Soviet control over Eastern Europe since the end of World War II has brought about a shift of unequaled magnitude in the East-West balance of power to the advantage of the Soviet Union. (Socor, p. 503.)

The Council of Mutual Economic Assistance is not a dramatic organization. Viewed from the West it lacks some of the glamor of the Warsaw Pact or the CPSU Congresses in Moscow or the new political force referred to as Eurocommunism . . . .

Evaluated on the eve of its 30th anniversary, there can be no doubt that the organization has made important progress, especially since 1970. The launching of the Complex Program in 1971 was followed, just two years later in 1973, by the world energy crisis which, from the viewpoint of Soviet and CEMA Secretariat objectives, could hardly have been more fortuitous. The upheavals of 1973 and 1974, and the worldwide inflation and shortages which will apparently continue for the foreseeable future, have given a tremendous boost to East European economic dependence on the USSR. It is difficult, of course, to measure the exact degree of this dependence and it is still in process of development. But added to the geographical, political and military ties which these countries already have with the Soviet Union, it is an impressive fact . . . .

As noted in this paper's introduction, CEMA is moving slowly but steadily forward. There are indeed many serious problems, just as the Soviet Union itself has many problems in its own economic development. It would appear, however, that at present time is on the side of "socialist economic integration" and that over the next two decades there is a good possibility that CEMA will become an increasingly stronger and more effective organization. (Smith, p. 173.)

### 3. *Does CEMA integration emulate that of the European Community (EC)? How do the East European integrative developments influence global, East-West and East Europe-United States Commercial relations?*

Our main conclusions can be summarized as follows:

Intra-CEMA trade prices were prematurely raised at the initiative of the Soviet Union to bring the USSR's terms of trade vis-a-vis Eastern Europe more in line with what they would have been if based on current, rather than lagged, world prices. The immediate effect of the rises in CEMA prices was to improve the USSR's terms of trade substantially but still by much less than would have been the case if current world prices had been applied.

The new price formula will not bring about fundamental changes in the intra-CEMA trade system and indeed could complicate the price formation process further without achieving compensating improvements.

Hard currency trade within CEMA does not appear to have expanded very much and is not likely to increase to the point where it will significantly alter the basically bilateral, barter-like character of trade among CEMA countries. (Kohn, Lang, p. 136.)

In other words, it is the mere existence of an enlarged EC and the success of several of its policies affecting trade with CMEA which serve as the incentive for the creation of a meaningful common socialist commercial policy and the distribution of power in CMEA which that implies . . . .

In conclusion, from an economic point of view it would seem that any foreseeable CMEA-EC agreement would have no major consequences for U.S. relations with either group . . . .

What will probably be much more important for these agreements is their implications for political trends in Europe and political relations between Eastern Europe, Western Europe and the U.S. The Soviets have an image for Western Europe just as they have one for CMEA, and agreements such as these are probably an important part of the realization of that image. (Hewett, p. 198.)

### 4. *Has economic reform revived as an East European issue? If so, in what form?*

The reform movement in Eastern Europe emerged because of dissatisfaction with the nature and results of the traditional Soviet-type economic system installed in the area after World War II. The struggle between pro- and anti-reform forces varied by country and led to different reform blueprints, incorporating diverse concepts of "decentralization" and dissimilar implementation strategies.

Throughout the area, there was a retreat from reform—earlier, faster, or farther in some countries than others. The reasons included interest group opposition, internal inconsistencies, insufficient slack, Soviet influence, and developments in the world economy. Only Hungary now has a significantly different economic system, although formal and informal central intervention in the

Hungarian economy is much greater than intended when the NEM was introduced in 1968 . . . .

Furthermore, the East European economies will remain heavily involved in CMEA, both because of Soviet pressure and because their ability in the short- or medium-term to restructure their economies toward more trade with the west is limited. Also, after their sobering experience with fluctuations in prices and quantities on the world since 1973, they appreciate more keenly the advantages provided by the stability of CMEA trade agreements. But, as explained above, integration in CMEA discourages economic reforms which differentiate the member countries' economic systems and give enterprises fulfillment of centrally-negotiated agreements.

Thus, expanded trade and investment relations with the West and CMEA are viewed chiefly as alternatives, rather than companions, to international economic reforms. (Bornstein, pp. 131-132.)

*5. Has the rate and structure of economic performance in Eastern Europe conformed to plans, expectations, and needs? Has defense been reduced as an onerous economic burden? Have any sectors or countries been especially dynamic?*

A review of the performance of the economies of Eastern Europe in the 1965-1970 and 1970-1975 periods taken in conjunction with their plans for 1976-1980 shows a generally declining trend for overall GNP (1965-1970 vs 1970-1975) and for overall NMP national income produced . . . .

Future growth in Eastern Europe will depend strongly on demographic factors, application of advanced technology, attitudes of workers and managers toward production, the related state priorities as to incentives via real wage increases and investment alternatives, and changes in the complex system of economic organization and planning that affect personal motivations for increased work effort and innovative approaches to production. The degree of success in financing imports of advanced production technologies and the up-to-date machinery and equipment to implement them will be an important factor in future performance . . . .

These problems are by no means peculiar to Eastern Europe, but they are exacerbated there by the expectations of the population encouraged by the claims of the socialist planners to catch up with and surpass the Western industrialized countries by measures of human welfare. (Alton, pp. 260-261.)

The military effort of the six East European countries covered in this study is indeed substantial: their number of regular active, well disciplined forces amounts to more than one-half that of the United States. Even in terms of the narrowly defined official defense budgets, the military expenditures of the six East European countries as a group amount to about one-fifth of the total defense outlays of the United States in terms of U.S. dollars. (Alton, Lazarcik, Bass, and Znayenko, p. 286.)

As to Yugoslavia . . .

Industrial production grew at a rapid but diminishing pace from 1952 to 1975. According to the official index, industrial output rose about nine-fold over this period, an expansion which corresponds to an average annual growth rate of 10.0 percent. (Moore, p. 486.)

*6. What have been the priority sectors? How has economic modernization in sectors such as automotive transport fared? Has energy supply been a constraining factor on growth? Are improvements in the consumers lot and exports tied to success in agriculture?*

The East European countries were informed by the U.S.S.R. in the early 1970's that oil deliveries in 1976-80 would be held to the 1975 level. This presented the East Europeans with a dilemma as they rely heavily on increased Soviet oil deliveries to meet their growing energy needs. The East European regimes first responded by planning massive imports of Middle Eastern oil but the explosion in world oil prices subsequently forced them to gear down these plans. In order to fill part of this growing energy gap, the East Europeans then launched programs to accelerate development of domestic energy resources and improve efficiency in fuel use. The burden was further eased when the U.S.S.R. relaxed its limits on oil deliveries somewhat to accommodate those East Europeans investing in Soviet resources development and those facing particularly serious economic difficulties.

Despite these adjustments, energy plans in 1976-80 are very taut with strains already appearing in 1976. If energy supplies fall short, the East Europeans probably will have to reduce economic growth goals. It is unlikely, however, that leadership will cut back planned improvements in consumer living standards very much. The U.S.S.R. is unlikely to provide much more oil in 1976-80 unless political stability in Eastern Europe is at stake. (Haberstroh, p. 379-380.)

The inability of the East European countries to satisfy regional needs for motor vehicle production from regional resources has a number of causes. Most importantly, the necessary production equipment, common vendor-supplied parts, and broadly diversified supporting industry is not available in Eastern Europe. The capability of the U.S.S.R. to supply these items is both insufficient to care for East European needs and not at the desired technological level . . . .

Cooperation with Western firms has allowed the East European motor vehicle industries to expand rapidly, despite major gaps in their domestic supporting industries. Today, these countries participate in the production of a wide assortment of trucks and passenger cars. Their contributions to production from domestic sources are growing and strengthening the import substitution value of their industries. (Edwards, Fraser, pp. 410 and 413.)

. . . Agriculture remains a critical sector in Eastern Europe in view of the rising populations and the sharply increasing demand for more and higher quality, protein-rich foods of animal origin.

After a relatively poor agricultural year for most of the East European countries in 1976, the outlook for the remaining part of this decade appears favorable, particularly for 1977. (Lazarcik, pp. 325-326.)

Experience has shown that large production units in Communist agriculture cannot on their own guarantee the concentration and specialization of production. To be effective, integration plans must be accompanied by other measures, particularly reductions in the range of products that the production unit (whether farm or complex) must deliver changes in management techniques. There must also be adequate investments in new machinery and technology, and sufficient numbers of trained personnel must be available. It is of course possible to impose integration plans on farms and enterprises before conditions are suitable, as is being done in some countries under discussion, but this is likely to lead to a waste of resources without achieving the anticipated benefits. Moreover, the available indications are that the big horizontally integrated enterprises are hardly more efficient than the smaller farms and enterprises they replaced. The task then for the East European countries implementing agricultural integration is not only to choose systems most suitable for their production within the organizational framework chosen. The latter task will undoubtedly prove more difficult to accomplish in the foreseeable future. (Jacobs, p. 355.)

During the past decade significant efforts have been made to increase the output and efficiency of Hungarian agriculture. Provision of greater economic incentives within the framework of the NEM, increased mechanization, the more intensive application of artificial fertilizers, as well as the spread of closed production systems in crop production undoubtedly have contributed greatly to the recorded output gains. (O'Relley, p. 374.)

### *7. How have the demographic trends and manpower supply affected economic policy and performance?*

According to the projections presented here, the population of Eastern Europe is expected to number between 116 million and 130 million by the year 2001. The principal determinant of the size of the future population will be the trend in fertility . . . .

Among the individual countries, Poland is expected to have the largest growth. The medium series projection for that country indicates an average annual growth rate of 0.8 percent between 1976 and 2001, compared to 0.7 percent for Romania, 0.6 percent for Czechoslovakia, 0.5 percent for Bulgaria, and 0.3 percent for Hungary. According to the medium series, East Germany will have almost the same number of people at the end of the century as in 1976. These varying growth rates are expected to produce only one change in the size ranking of the six countries—East Germany will drop from third place to fourth place and Czechoslovakia will move up to third sometime during the late 1990's." (Baldwin, pp. 424 and 426.)

The reason for the current interest in the employment of foreign workers is related to the growing utilization of the labor supply in the COMECON countries. In most of the Eastern Block countries the growth of the labor force has slowed in the 1970's. Especially in the GDR (German Democratic Republic), Czecho-

slovakia and in Hungary, but also in certain branches and areas of the Soviet Union, an acute lack of labor is becoming apparent. Only in Bulgaria, Romania and Poland is the number of the employed in nonagricultural jobs increasing in the 1970's at the same rate as in the 1960's. Because of the varying degree of the utilization of labor reserves, it is plausible to consider the temporary migration of labor as a means of eliminating the labor shortage. . . .

In conclusion, it must be remembered that the employment of foreign workers within COMECON differs in many respects from the problem of guest workers in the West. The scale of the employment of foreign workers in the East is significantly lower, so that one can hardly speak of an influence of these workers on the economic development of the host country. Whereas in the West, in some developed industrial countries the fraction of guest workers within overall employment is so large that it represents a real growth factor. (Levcik, pp. 458 and 474-475.)

*8. What are the common and unique factors in the economic policies, institutions and performance of the nations in Eastern or Central Europe, including the six core members of CMEA, Yugoslavia and Albania? How have these factors changed over time, with special emphasis in the recent five year period? What are the relative short and long term prospects for change and success in economic development?*

Paul Marer has provided an overview of a series of individual country studies (pp. 523-566): *Albania* (Schnytzer and Kaser, pp. 567-646); *Bulgaria* (Allen, pp. 647-697); *Czechoslovakia* (Holesovsky, pp. 698-719); *GDR* (Keren, pp. 720-765); *Hungary* (Portes, pp. 766-815); *Poland* (Fallenbuchl, pp. 816-864); *Romanian Foreign Trade* (Montias, pp. 865-885); *Romania* (Jackson, pp. 886-940); *Yugoslavia* (Tyson, pp. 941-996).

Based on 1970-75 performance, the eight countries can be divided into two groups; the three relatively fast-growing countries of Romania, Poland, and Bulgaria, and the less rapidly growing other countries. Taking the 1965-76 actual and 1976-80 plan figures into account, Romania can probably claim the first place and Bulgaria second.

Interesting to note is the position of Yugoslavia and Albania. Yugoslavia places right in the middle, during 1975-76 performing about the same as Hungary. During 1965-70 Albania claims to have grown roughly on a par with Romania and Bulgaria, but its growth slowed during 1970-75 and its performance was roughly on par with that of Hungary. To be sure, Albania's exceptionally poor and incomplete statistics and the absence of a Western recalculation undermines our confidence in the data and makes it particularly difficult to compare its performance with those of other countries. . . . (Marer, pp. 535-536.)

To provide an overview for the eight East European countries on these issues, the task is more manageable and the comparisons more meaningful if the countries are divided into two groups: the Southern Tier, comprised of the Balkan countries of Bulgaria, Romania, Yugoslavia and Albania, which on the basis of official statistics, have been growing more rapidly than the rest of Eastern Europe (except Poland), and the Northern Tier, comprised of the more high developed by still very diverse nations located to the north of the Balkans, the GDR, Czechoslovakia, Hungary and Poland. . . . (Marer, p. 554.)

For the GDR, its ambiguous relations with the Federal Republic of Germany (FRG) are the chief determinant of its economic policy: "the GDR cannot help but feel that it is taking part in an unending economic race on whose outcome the very stability of the GDR may depend." (Keren, p. 721.) The GDR cannot permit itself to fall far behind the FRG in consumption standards, a consideration underscored by the Polish riots in December 1970 which led to a reassessment of the consumer's place in East Germany's development policy.

This dilemma also conditions the GDR's relations with the Soviet Union and the rest of CMEA, where its potential weakness vis-a-vis the FRG gives it strength and leverage. (Keren, p. 722.)

For Czechoslovakia, the restoration of economic normalcy and control became the chief determinant of economic policy after 1968; the country seems to be characterized by an absence of any new economic strategy or policy initiative.

Hungary has been occupied with guiding its economy within the framework of its comprehensive economic reforms, with reasonable success, as is argued in the essay by Portes.

Poland is the site of one of the world's most notable new developments since 1970: adoption of a rather extreme version of import-induced growth as a development strategy, with a large part of imports financed by credits. Two environmental considerations, external and internal, played a large role in inducing this new strategy. The external one was the signing of a "normalization treaty" with the FRG in December 1970, followed by the Soviet-American detente of the early 1970's which created a climate conducive to reorientation toward the West. The internal consideration was the confrontation in December 1970 between the workers and the government following the rise in food prices. The government then acquiesced in the combined demand of the workers' price freeze and substantial wage increase. This in turn ruled out an acceleration of investment growth based on internal resources—the strategy followed by Gomulka—and ushered in the import-induced growth strategy of Gierek, initially planned on a moderate but realized in a rather extreme version, as discussed by Fallenbuchl (Parts I-III). . . . (Marer, pp. 560-561.)

Two of the common, and in several countries the most serious, problems that remain to be solved are: (1) how to restore the economic imbalance created by the rapid rise in hard-currency imbalance created by the rapid rise in hard-currency indebtedness and other obligations, and (2) how to improve the efficiency of production, since productivity must generate a larger share of growth to compensate for slowdowns in the rate of growth of factor inputs—capital and labor. The two problems are interrelated . . . .

On the problem of improving the efficiency of the economy, all countries face difficulties. The systemic and organizational obstacles to improved efficiency are well known problems. It must also be recognized that the change from a predominantly agricultural to a largely industrial society has been so rapid in the Balkan countries (and to some degree in Hungary and Poland) that most workers are only one generation or less removed from agriculture. Consequently, the quality of the non-agricultural labor force is poor, which may now be a major factor hindering improved productivity . . . .

To improve productivity, a renewed emphasis has been placed in all countries on technological innovation and on reducing the share of labor-material and fuel-intensive products in output.

In the short to medium run, numerous factors external to the economies of the East European countries will affect their performance and prospects. But in the longer run, their economic performance will be decided largely by their ability to overcome systemic limitations to productivity improvements. (Marer, pp. 563-565.)

### *9. What new commercial and institutional relations have recently emerged in East-West trade, including relations between the individual nations and the United States?*

The CMEA countries are trying to overcome their relative isolation from the world economy, and to institutionalize their increasing economic relations by agreements with, or membership in multinational organizations. At present, however, these efforts are somewhat overshadowed by the developing countries' increasing urgent demand for a reorganization of the international economic order and by the expanding complex of negotiations and relations among the Western industrialized countries and the Third World. Yet, the international economic weight of CMEA members has become too great to discuss new forms for international economic relations without taking into consideration the needs of the State Trading countries . . . .

A further result of integrating CMEA countries in world economic organizations can be found in the fact that the institutions which were originally founded by the industrialized countries could cease to fulfill their original purpose (uniform articulation of interests to the outside, obligatory solution of problems within) because of divergent interests and economic systems. Under these conditions, these organizations would form a generally acceptable and thus broad context within which various regional and/or multipolar interest groups agree upon binding and functional arrangements. For this reason it would seem from the point of view of the Western industrialized nations that the inclusion of countries with lower levels of development and/or other social systems would only be plausible if at the same time an institutionally secured and strengthened formulation of their own interests can take place, for instance, within separate organizations (such as OECD), or by building factions within global organizations (such as the Club of Ten within the IMF).

In this context it seems conceivable that the OECD could cover institutionally the following subjects:

Formulation of a joint strategy *via-a-vis* CMEA countries and development of joint regulations for the conclusion of trade and cooperation agreements with them.

Safeguarding of reciprocity in trade relations with CPE's;

Determent of unfair trade practices (e.g., dumping).

Evaluation of possible effects of indebtedness.

Promoting multilateralization of East-West economic relations, and coordination of bargaining positions within multinational organizations.

Effectuating that the CMEA countries bear their share of obligations to the Third World.

Institutional relementations of East-West economic relations could also be imbedded in a new international order. In this context, the historical ideas on the creation of an International Trade Organization could be reconsidered. Such an organization could not only work on the solution of GATT problems, but also on problems of capital transfer, ("GATT for investment") and raw material supply.

Chances for such developments however appear to be slim. (Baumer, Jacobson, pp. 999 and 1018.)

Over the last decade, East-West commercial exchanges between market and non-market economies have increased in both volume and complexity. From simple trade transactions, these exchanges have evolved to include licensing, co-production, joint marketing, and even joint equity ventures . . . .

The progress which has been achieved in recent years, both before and after the signing of the Helsinki Accords, in the exchange of economic information, provision of business facilities, and stimulation of industrial cooperation has come about primarily through the efforts of the joint commissions. There is no doubt that the commissions can plan a significant part in furthering the implementation of the Helsinki Final Act. The joint commissions provide each of the signatories a mechanism through which they can strive bilaterally towards accomplishing its goals. Although the bilateral character of the joint commissions may involve much duplication of effort and prove less efficient than multilateral efforts, the work of each commission should reinforce the efforts of the others and thus hasten fulfillment of both the Final Act's and the commission's objectives. Concerted effort to implement the guidelines and recommendations of the Final Act, in turn, cannot help but infuse added vitality and effectiveness to the life of the joint commercial commissions. (Lotarski, pp. 1019 and 1041.)

Generally favorable policy changes in both Eastern and Western Europe have encouraged the growth and changing structure of intra-European East-West trade over the past decade. An ever greater proportion of East-West trade between the WE(12) and CMEA(6) consists of manufactured products. The sharp decline in the importance of CMEA (6) agricultural exports and the equally dramatic increase in manufactures exports reflects a significant transformation of East European export opportunities and capabilities. In the period 1965-1975 West European exports to CMEA(6) grew at an above average rate, but the East European countries on the whole were unable to increase their share of total WE(12) imports. These contrasting trends are reflected in the deteriorating intra-European East-West trade balance of the CMEA(6) countries. We suggested that a number of factors may help explain the relative stagnation of East European exports. Also noted was the intense competition among WE(12) countries for Eastern markets. At the policy level this is reflected in the growing importance over the past decade in governmentally-backed export credits in East-West trade. In the trade statistics this competition is apparent in changing export shares. In the past the degree of competition among the CMEA(6) for export markets in Western Europe has seldom been discussed. This competition could intensify in the post-Helsinki period, however, if in the context of increasing CMEA(6) indebtedness and continuing trade balance deficits, the East Europeans decide to make a determined effort to compete in more than a residual manner on a variety of West European markets. Whether East European balance of payments and indebtedness constraints will lead to a relative slowdown in the growth of intra-European East-West trade remains to be seen. (Wolf, pp. 1053-1054.)

### *10. What Western commercial practices have tended to foster or constrain the development of East-West trade?*

Unsatisfied Soviet and East European needs for Western technology, manufactured goods, and grain remain large, holding the prospect of enlarging Western

exports in the years ahead. Needs, however, are not the sole determinant of trade. Over the long term continued growth of East-West trade must rely on an ability of the East European countries to expand their hard currency earnings exports to the West, rather than on continuing the increase in the debt that has fueled much of the recent growth of Soviet and East European imports . . .

Rather, we believe that Soviet/EE ability to increase imports is, in the longer term, inevitably largely dependent upon an expansion of the dollar value of their hard currency exports to the West. Ability to accomplish this expansion is, in turn, dependent on at least four basic factors:

Increasing the physical volume of products available for export

Increasing penetration of Western markets, i.e., successfully selling increased quantities to the West

The rate of Western inflation

The terms of trade (the relationship of import to export prices) (Lenz, Kravalis, pp. 1057 and 1128.)

This paper has described the various import protection systems employed by selected Western countries. What generalizations can be made about these protective systems?

First, it can be said that none of the countries covered by this paper have left themselves defenseless.

Second, no country relies on a single instrument; all have several tools available to them.

Third, all the countries observed employ *ex ante* protection to varying degrees. The most restrictive of the types of *ex ante* protection are probably the discriminatory quantitative restrictions employed by the Western European countries, the denial of MFN by the United States, and the generally high Austrian tariff rate.

Fourth, all the Western nations covered by this paper maintain both general and special and protective systems against imports from state-controlled economies (although in the Austrian case this is not explicitly stated in the legislation.) In no case are the general and special systems for imports mutually exclusive—in other words both general and special measures can be employed against imports from state-controlled economy countries.

Fifth, an important feature of the various *ex post* protection systems is the degree of restrictive potential which has not yet been utilized. Given the number of instruments available both for general and special protection against communist imports, restrictive actions have been relatively restrained. Of course, this may be due partly to the protection provided prior to the fact of importation by the *ex ante* protective systems. (Taylor, pp. 1171–1172.)

### 11. How have East-West industrial cooperation (EWIC) and other new institutional forms influenced commercial relations?

Increasingly, however, industrial cooperation has become the generic term for a type of relationship which may occur at various levels, and the remaining terms have been reserved to denote variants of it, usually at the enterprise level . . .

Trade and technology transfer under EWIC agreements continue to face formal Western import barriers and export controls. While Western tariffs and quotas have on average been significantly reduced, they remain important in some sectors. They and other non-tariff barriers hit hardest at manufactures, which are the principal object of EWIC agreements. In the field of customs duties, preferential treatment for industrial cooperation has not been introduced in any Western country. On the Western side, the possibilities of tariff advantages have been limited to existing facilities, such as occasional exemptions and relief, temporary admission procedures, and so forth. These have been of limited usefulness. The Eastern countries have sought to gain improved access for cooperative exports through bilateral agreements with Western governments, and have succeeded in some instances in obtaining special quota exemptions for such products. Eastern countries have also granted customs preferences, especially in the form of duty-free entry for Western intermediate products which are re-exported after processing. (McMillan, pp. 1177 and 1218–1219.)

Countertrade is generally understood to mean a set of transactions wherein the hard currency claim on a communist country resulting from an import from the West is offset by a complementary or balancing Western purchase of Eastern products. In most countertrade transactions (the exception is barter) the Western good is not directly paid for by the Eastern good. Rather, the Western export is financed partially or in full by Western credit on a contract denominated in

hard currency, while the subsequent Eastern exports, under separate contract, generate hard currency that can be used to make payments against Western credits . . . .

It can be expected that countertrade will remain an important component of the East-West commercial relationship through 1980. A substantial growth in Eastern ability to export without the crutch of countertrade, or an increasing use by the communist countries of other financing techniques could diminish Eastern reliance on countertrade. However, it seems unlikely that this will happen during the next several years. More likely, the Eastern countries will continue to press Western firms for more and more countertrade, with increasing emphasis on compensation arrangements. Western firms, on the other hand, will continue to accede to Eastern countertrade demands in those situations which they perceive the individual transactions involved to be profitable. (Matheson, McCarthy, Flanders, pp. 1278 and 1303.)

The approach to economic and industrial cooperation varies from country to country depending on its motivations and particular economic aims. For example, to encourage long-term infusion of Western technology, management and capital, Romania has sanctioned the formation of joint venture enterprises on its national territory. While other communist countries do not permit the full joint ownership and management rights embodied in such joint ventures, they are receptive to other types of economic and industrial cooperation, and in some instances have adopted modified joint venture schemes. Hungary, for instance, has passed a law which permits economic cooperation between Hungarian and foreign firms whereby there is no equity ownership by the foreign investor, but the foreign party is allowed to invest in the joint company, participates in management and shares in company profits. Bulgaria, on the other hand, will not allow Western capital investment on its territory but permits profit sharing from joint cooperation activities. Most recently, Poland passed legislation which opens the door to foreign investment in certain domestic industrial enterprises. (Verzariu, Burgess, p. 1225.)

While a long-term cooperation agreement with the U.S. Government has been longer in coming, the Romanian Government has actively and energetically pursued the topic of cooperation with American firms in a number of different forms over the past several years. Recent meetings of the Joint American-Romanian Economic Commission endorsed the development of economic cooperation between the two countries including the establishment of joint ventures. (Burgess, p. 1246.)

Our analysis suggests that the decentralization of Romanian foreign trade activities was a properly conceived organizational response to the needs of Romania's international strategy of increased trade with the west and of expanded exports of manufactured goods. However, the decentralization was not successful and was eventually abandoned due to internal shortcomings including the inability to provide skilled personnel to operate the new organizations and because of the hostile external environment which greeted the new organizations.

Despite the decentralization, Romania does not appear to have abandoned its foreign trade strategies. However, because the current centralized organization does not appear to be appropriate for this strategy, we anticipate that either strategy or organization or both will be subject to further experimentation. One possibility, alluded to in Section III, is the possible use of cooperation to overcome the defects of the current organizational form. Whether cooperation can fulfill these hopes or not is, however, a question only the future can decide. (Brada, Jackson, p. 1276.)

12. *Financing increased commercial relations poses both unique and common problems for the countries of East Europe. How they have dealt with their balance of payments problems? How critical has short, medium, and long-term credit been to the trade levels of the countries of East Europe? With limits on the Eastern country disclosure of indebtedness how can accurate Western assessments be made?*

Heavy borrowing has pushed the hard currency debt of the East European countries up from \$5 billion at the end of 1970 to \$26 billion by yearend 1976. Although these countries had programmed large increases in capital goods imports to be financed largely with Western credits, indebtedness was not expected to reach such proportions. Soaring world commodity prices, the economic recession in the West, and extraordinary grain imports added greatly to the borrowing already planned by the East Europeans to help fuel economic growth.

With heavy debt burdens and continued uncertainties in their Western markets, the East Europeans are faced with difficult choices. In order to keep new borrowing down, they will have to carefully monitor imports from the West while attempting to maximize exports. Since economic growth depends to an important degree on imports of Western capital goods and industrial materials, cutbacks in import growth will impact negatively on the economic health of the East European countries. Maintaining a modicum of growth in consumer welfare will be necessary in order to minimize consumer discontent . . . .

A critical problem facing the East European leaders is how to keep up the imports of the industrial materials, agricultural products and consumer manufactures deemed necessary to meet economic growth plans and consumer requirements. Under the most favorable conditions—a strong recovery in exports and good harvests—most East European countries should be able to import the necessary industrial materials without economic or financial assistance. But they can do this only if they are willing to curb their imports of machinery and equipment. All the East European countries have, in fact, indicated their intention of allowing little if any growth in (or even cutting) imports of Western capital equipment. Such imports can be curbed for a time without much effect on economic growth, especially in Poland where there is a large backlog of equipment not yet in operation.

If recovery in the West is sluggish, the East Europeans face the prospect of having to cut back their economic growth. Poor harvests would make this all the more necessary. Under these circumstances, it is unlikely that the East Europeans could import the necessary industrial materials without outside help. The East Europeans' tendency to overstockpile will ensure an adequate supply of industrial materials for perhaps another year, but thereafter failure to raise imports would result in serious bottlenecks in production.

Moscow apparently is concerned about Eastern Europe's economic difficulties—especially those which threaten political stability—to provide some assistance, even at the cost of some of its own hard currency exports. Gierek's recent success in obtaining a large Soviet aid package—including additional deliveries of oil—could set the stage for assistance to other East European countries. Such aid probably would consist mainly of above-plan deliveries of raw materials and permissions to continue running deficits in trade with the U.S.S.R. The Soviets also might extend some hard currency credits, but these are not expected to be large. Whatever assistance they provide, however, probably will not be sufficient to free Eastern Europe from the need to closely control imports. (Zoeter, pp. 1351 and 1361-1362.)

Estimates of East European indebtedness in hard currency are founded on a few main sources of information. The two most important are quarterly reports by the Bank for International Settlements (BIS) of the assets and liabilities of commercial banks in 11 Western countries and data issued by the export credit guarantee organizations of Western governments. Other sources include occasional information on bank assets and liabilities from Western countries not reporting to the BIS; West German reports of the cumulative balance on clearing account with East Germany and on "official" long-term assets with the rest of Eastern Europe, reports by U.S. government agencies on outstanding credits given to finance agricultural exports; and data or the International Bank for Reconstruction and Development (IBRD) and the International Monetary Fund (IMF) on sums advanced to Romania. Published sources do not cover credits held by Western suppliers at their own risk, a *forfait* credits held outside commercial banks, and outstanding hard currency claims of East European countries on Western customers, but partial estimates can be made. Estimates are not included for East European indebtedness in hard currency to CEMA's International Bank for Economic Cooperation (IBEC) and International Investment Bank (IIB).

The above remarks apply generally to the sources and limitations of CEMA countries' indebtedness, including those of Lawrence Brainard, formerly with the Chase Manhattan Bank and presently with Banker's Trust; Professor Gaetano Stamatii, President of the Banca Commerciale d'Italia; and those of Janos Fekete of the National Bank of Hungary. All such estimates reflect chiefly information that is widely circulated, most of it published. To be sure, confidential information is also used to bridge some of the numerous gaps in information. But it is now true, as it was not until quite recently, that most of the data needed are published. (Melson, Snell, p. 1370.)

13. *Do individual nations have unique commercial relations? How about Poland—the largest economy? And Albania, probably the most unique? Is the independent foreign political policy of Romania carried over to its foreign economic policy?*

The formation of the East-West Foreign Trade Board was a direct result of an amendment to the Trade Act of 1974 by Senator Long. The purpose of the amendment, as stated in the Congressional Record of December 12, 1974, "is to establish within the executive branch an interagency board to coordinate and oversee the orderly development of trade with nonmarket countries." . . .

With Secretary of the Treasury Blumenthal as Chairman of the Economic Policy Group as well as the East-West Foreign Trade Board, East-West trade policy is assured the strength of a coordinated role in U.S. Government activities. In addition, the Secretary's membership in the National Security Council fulfills the Board's mandate to monitor trade to ensure that it is in the best national interests of the United States. (Searing, pp. 1347 and 1349.)

Well before the issue of East-West trade became topical in the United States, the Chamber of Commerce of the United States had begun studying the opportunity for trade with the Soviet Union and Eastern Europe and the role the Chamber might play in helping the U.S. business community take advantage of the considerable potential for trade with this part of the world. The uniqueness of the Eastern European trading system, together with the widely held perception in the U.S. that progress in the commercial field must necessarily await progress on political issues, had inhibited a great number of U.S. firms from even considering the opportunities the Eastern European market had to offer. With the exception of a few experienced East-West traders in the United States, these opportunities were going to enterprising firms in Western Europe.

As some of the rigidities of the U.S. relationship with Eastern Europe began to disappear in the 1960's, U.S. business interest in Eastern European markets developed apace. Following an opinion survey which indicated overwhelming support for expanding trade with Eastern Europe among Chamber membership, the Chamber of Commerce decided to embark on efforts to stimulate discussion within the U.S. business community on East-West trade issues. In this context, the Chamber became the first organization of national prominence to come out unequivocally in favor of nondiscriminatory tariff and credit status for the Eastern European nations. (Wilson, Hasfurther, p. 1341.)

Since taking power in late 1970, the Gierk regime has imported massive amounts of Western machinery and technology to support an ambitious economic development program. However, Warsaw imported much more than originally planned, largely because of (a) above-plan imports of capital equipment, (b) unanticipated imports of Western grain in 1974-76, and (c) higher prices for imported goods. Although exports to the developed West increased, they did not keep pace with imports. The resulting huge trade deficits forced Poland to borrow more heavily than expected and pushed its net hard currency debt up from \$2 billion at yearend 1973 to \$10.2 billion by yearend 1976 . . . .

In the final analysis, Warsaw will be forced to cut its planned economic expansion program. The cuts will have to be handled carefully to minimize their effect on consumers and exports. Just how much freedom of action Polish leaders have in controlling imports that directly or indirectly affect consumption is uncertain, given the sensitivity of the population to any real or perceived reductions in its standard of living. Warsaw could ask Moscow for further assistance which could soften the impact of any reduction in planned growth. But, Moscow probably would want some sort of a *quid pro quo* in return for any aid. The Soviets probably would not press for greater Polish deliveries of hard goods—such as coal—because this would only aggravate Poland's payments position. At the very least, Polish leaders may feel more obligated to heed Soviet advice concerning management of the Polish economy. (Teske, pp. 1312 and 1322.)

Albania has always traded most with the donors of economic assistance. While this pattern is not untypical of relations prevailing between developing and developed countries, the fundamental framework has always been political. Before World War II, the dominant trading partner was Italy, which supplied 43 percent of Albanian imports in 1938 and provided the biggest export surplus to Albania

(covering 30 percent of its total deficit). The relationship became still closer during the Italian occupation (1939-43). Liberation in concert with Yugoslav partisans naturally led to intimate economic ties with postwar Yugoslavia. As has just been noted, Yugoslavia furnished assistance until 1948: in 1945 it monopsonised Albanian exports although furnished only 28 percent of its imports. The shift to Soviet and Comecon aid after 1948 greatly raised the share of that group, as the following Comecon percentages of Albanian trade show:

Year:	Imports	Exports
1950.....	100	98
1960.....	86	92
1963.....	32	39
1964.....	28	47

The contrast between the overwhelming trading links with Comecon in the fifties with their diminution after the turn of the decade reflects the termination of Comecon aid and the total break in Albano-Soviet commercial and diplomatic relations. The other members of Comecon did not, however, cease to trade. . . .

When silence enveloped the Albanian trade returns in 1964, China was supplying 63 percent of Albanian imports and buying 40 percent of its exports. The second largest partner among Comecon members was Czechoslovakia (10 percent of imports and 19 percent of exports). . . . (Kaser, p. 1328.)

14. *If the tariff restrictions were reduced, that is if Most Favored Nation treatment were extended to the nations of East Europe by the United States, how much might the exports from East Europe be increased? What other legislative and institutional barriers to increased commercial relations might be removed?*

At present, the United States is the only major Western industrialized country which has not granted Most Favored Nation (MFN) tariff treatment to all of the communist countries discussed in this paper. Poland has been receiving MFN treatment from the United States since 1960, and Romania since mid-1975. None of the other communist countries receives MFN from the United States.

Official representatives of the Soviet Union, and of other Eastern European communist countries that do not receive MFN treatment from the United States, frequently assert their belief that the granting of MFN would enable their countries to increase greatly their exports to the United States. In addition, they see in MFN a political signal or more relaxed relationships. . . .

Western tariffs are being slowly lowered, on the whole. It is rare for a tariff to rise. The Kennedy round of tariff cuts in the MFN rates of the GATT members promises to be succeeded by the Tokyo round. If the United States maintains its column 2 (non-MFN) rates intact, and fails to grant MFN to those communist countries that do not now have it, more and more of the affected CMEA goods may be expected to seek outlets in other Western markets. From the tariff point of view alone, as time passes without the granting of MFN by the U.S., the U.S. share of tariff-sensitive CMEA country exports would be expected to fall; if then, MFN is granted at some future time, the proportional rise in U.S. import share would be so much the greater—especially since the U.S. MFN rates would also have fallen in the meanwhile.

But quantitative restrictions change the whole picture in an unpredictable way. Unilateral quotas of various types, bilateral agreements, and multilateral guidelines all restrict the trade in any specific category of product for any reason of national interest. European Community restrictions on foodstuff imports suddenly lead to surges in CMEA sales to other I.W. countries, and there is a reverse effect when the U.S. negotiates quotas on footwear. No matter how strong the statistical indicators of tariff sensitivity may appear to be, the repercussions of granting MFN can be quickly modified, and the econometric predictions negated, by market disruption proceedings. (Raffel, Rubin, Teal, pp. 1396 and 1421.)

#### DATA AND STATISTICAL RELIABILITY

More information is now being published on the economies of East Europe. An annual statistical handbook for the member countries of CMEA is now being published. Moreover, considerably more information is being provided through international media, such as the ECE,

bilateral government commissions, and private Western commercial and financial channels. However, even by compliance with the Helsinki agreement, the data disclosed still falls far short of that commonly available among Western trading nations.

This lack of data raises the cost and risk for Western corporations dealing in Eastern markets. Especially important for governmental and commercial banking institutions is better information on the balance of payments, outstanding debts (especially in hard currency areas) and financial assets. These detailed data were not covered explicitly in the Helsinki agreements. However, Western commercial and banking interests have made progress in reconstructing the necessary data and publishing it. Reliable data is still needed to answer the legitimate questions of commercial and financial interests in the West:

- (1) What are the current and future East-West market prospects?
- (2) How much is owed to other creditors by a debtor nation?
- (3) What are the debtor nation's other assets if deliveries cannot be made as agreed?

In assessing economic performance in East Europe, there are still differences in methodology. Western concepts of national accounting require adjustment of data reported by the statistical agencies in East Europe. The methodology used in this compendium by Thad P. Alton and associates builds on that of Maurice Ernst (in his studies of East European accounts) and Abram Bergson (in work on Soviet accounts). The necessity to estimate for missing data and to make subjective judgments precludes the development of a fully defined, objective set of accounts. However, the reconstruction of Thad Alton and associates probably best parallels those national accounts compiled by Western economists for the Western industrial nations. As the statistical reporting of the East European nations improves in coverage and comparability, more reliance may be placed on the primary source data. The methodology of estimating Eastern indebtedness used in this volume illustrates the progress and differences that still remain. Joan Zoeter and Edwin Snell have some differences as the reader may observe. Some authors use figures of Lawrence Brainard developed at Chase Manhattan and Bankers Trust. More participation of Eastern bankers and economists would help to further improve the data and reduce the differences in opinion and methodology.

#### PROBLEMS AND PROSPECTS

The proliferation of economic claimants for goods and services runs well ahead of the ability of the output increases to satisfy demands. Modest economic growth in the face of rising expectations is not unique to East Europe. However, the options for improved performance are especially limited, and the mixture of costs and benefits, particularly complex. For example:

- (1) Imports from the West may facilitate improvement in the quality of output and generate exports capable of earning hard currency. However, levels of imports are sharply restricted by balance of payments deficits, and exports compete with orders from the Soviet Union and their own domestic economy.

(2) Increased priority to agriculture and consumer goods output may provide incentive for higher labor productivity and increasing real income for political stability. However, investment resources may not be easily shifted from defense and export industries to modernize and expand consumer related activities. Likewise, modest economic growth limits the incremental resource supply to be shared among the various resource claimants.

(3) Tourism and other invisible earnings may provide more hard currency needed to expand Western imports. However, investment in tourist facilities may compete with needed domestic programs, and conspicuous tourist expenditures may increase consumer dissatisfaction even though real incomes are rising.

The above choices still present too pessimistic a picture of East European economic prospects. Although the economies of East Europe are small, have insufficient raw materials and human resources, suffer from a technology lag with their Western neighbors, and must satisfy a revolution in rising consumer expectations, they do have assets. Many of their current leaders and planners are pragmatic and flexible. Many of the Eastern economists, statisticians, bankers, and managers are ingenious and highly professional. Central or Eastern Europe has always survived by persistence, ingenuity, and determination when surrounded by superior political and military powers. In spite of its precarious position between economic colossuses, the Soviet Union in the East, with its raw material monopoly, and the Common Market, Japan and the United States in the West, with their formidable technological leadership, East Europe may not only survive, but prosper.

Part I. POLICY AND PERFORMANCE

---

---

## EASTERN EUROPE: POLITICAL CONTEXT

BY IVAN V. MATUSEK

The latent instability always present in Eastern Europe<sup>1</sup> recently surfaced once again affecting most countries of the area. Rooted in the long suppression of civil rights, national aspirations and values and complicated by economic grievances, the challenge posed by dissidents to those in power has startled local authorities, alarmed their Soviet overlords, and raised new doubts among Western observers about the long-term ability of the existing Communist regimes to govern their populations. The question is not so much whether existing leaderships would be toppled—although in some countries this possibility cannot be altogether ruled out—but rather whether the system can adjust to cope with such pressures. Is it willing and/or able to react in an enlightened fashion, or will it regress into positions reminiscent of policies prevailing during the “cold war” days: severe repression at home and bitter hostility towards the West in foreign relations? In effect, will it jettison detente?

A case can be made for the conclusion that popular and official reactions to detente are indeed at the root of East Europe's recent troubles. The Final Act of the Helsinki Conference on Security and Cooperation in Europe (CSCE) to which all the regimes (except Albania) subscribed raised popular expectations throughout the area for a more decent way of life: freedom to travel to the West, greater exchange of information through availability of Western publications, and greater toleration on the part of the authorities toward such human rights as the freedom of expression, religious belief, and right of dissent and petition. Dissatisfaction with the rate of improvement in the standard of living was a major factor in some countries.

The atmosphere of new expectations and the known disparities in quality of life between the Western and Eastern parts of Europe caused considerable embarrassment to the authorities on the eve of this year's Belgrade Conference which is to review implementation of the provisions of Helsinki's Final Act by the 35 signatories.

The events—which amount to a challenge to Communist authorities—have by now directly affected the three northernmost countries—Poland, East Germany and Czechoslovakia—and evoked echoes in Hungary, Romania, Bulgaria, and Yugoslavia. A common trait in all is the hunger for denied human rights which the dissidents have articulated in petitions or manifestos and the awareness that similar demands are also being voiced in the USSR. In addition, the support and sympathy coming from West European communists, socialists and a number of Western governments give encouragement to the dissidents and reaffirm their belief in the righteousness of their cause.

---

<sup>1</sup> The term Eastern Europe encompasses eight countries: Albania, Bulgaria, Czechoslovakia, East Germany, Hungary, Poland, Romania, and Yugoslavia.

The first country to be affected was Poland where an ill-advised attempt in June of 1976 to introduce massive price increases triggered workers' strikes and riots which could have toppled the Gierek regime were it not rescinded the very next day. This left the regime leaders weakened and in search of policies which would cope with economic realities while assuaging the ugly mood of the country. The regime sought a solution through a revision of its Five Year Plan (1976-80), scaling down the share of GNP earmarked for capital investment, increasing availability of food and housing, and pledging not to increase food prices for at least a year and then only after "consultations" with the workers. In order to increase the availability of goods and services for the populations the regime proposed an ideologically unorthodox promotion of private enterprise in the services sector and in agriculture. The new policy of consumerism appeared to have the approval of Moscow which also extended financial assistance.

The regime, however, started offering these carrots only after it had moved repressively against the workers who rioted in several cities: arresting some three hundred and dismissing about a thousand others from their jobs. As a result, a new bothersome situation arose. A group of well-known Polish intellectuals formed a Workers' Defense Committee which started collecting funds in order to assist the workers and their families to defend themselves against authorities who, it was claimed, were encroaching upon workers' rights. As the regime moved to harass and neutralize the group, the powerful Catholic Church took up their cause, attacking the regime from pulpits not only on this issue, but also for its denial of unhindered development of church life.

Apparently stalemated and fearing a potential coalescence of the three opposition groups, the regime proclaimed a conditional pardon for the arrested rioters and began to rehire the dismissed workers. In so doing it not only revealed a desire to avoid further disturbances at home but was also taking account of the significant amount of sympathy and support the movement evoked in the West.

In the two other countries—East Germany and Czechoslovakia—popular grievances and the resulting dissidence are nearly exclusively of a political nature. Both countries have traditionally enjoyed a much higher standard of living and relatively well-stocked shelves. Their grievances have to do with the oppressive and inhumane nature of the system. For example:

In East Germany, the regime has been unwilling to permit its citizens to travel to visit or join their relatives in the Federal Republic of Germany and the West in general; and, in addition, it has imposed on the many believers in this land of Luther restraints and prohibitions on the practice of their faith;

In Czechoslovakia, the intellectuals and citizenry sorely miss the democratic institutions that they cherished in the inter-war period and are depressed by the suppression of the popularly-shared aspirations to establish a "socialism with a human face" which were crushed by the Soviet-led invasion of 1968.

Since the August 1976 self-immolation of East German Pastor Bruesewitz, several leaders of the Evangelical Church have undertaken a self-critical, soul-searching reevaluation of its role in East

Germany. Its bishops issued a pastoral letter, read from pulpits throughout the country, which attacked the regime's official characterization of Bruesewitz's suicide as "an act of a madman" and associated the church with his unhappiness and deep concern over the education of East German youth and the Church's future under the system.

Nearly simultaneously, the expatriation of a dissident poet and songwriter (Wolf Biermann), following a performance in the FRG, caused more than one hundred East German artists and writers to sign a document protesting the authorities' action against Biermann. The regime reacted by arresting a few of the signers and harassing others, but most of the protestors apparently got by with only a warning. The main concern of the regime was the some 100,000 applications for emigration or travel to West Germany or the West. These were denied or simply not acted upon, and the regime increased its harassment of those underterred by the signals it was passing to the citizenry.

In Czechoslovakia, the challenge to the authorities was more specific and direct. At the turn of the year some 250 writers, journalists, academicians and expoliticians, most of whom were associated with the "Prague Spring", issued—and distributed at home and abroad—a document titled "Charter '77." The document is a human rights manifesto and accuses the regime of not honoring the obligations it assumed by subscribing to the Helsinki Final Act and to the two UN Human Rights Covenants which it has ratified and thus incorporated into its own legal code. The manifesto, which has since January 1977 nearly tripled the number of its original signatories, is clearly aimed at embarrassing the regime before world opinion just prior to the forthcoming "Belgrade 77" conference which is to review the signatories' fulfillment of the obligations contained in the Helsinki Final Act.

The timing of this action left the Prague authorities in a quandary: should they suppress the dissent and face criticism for their action at the "Belgrade 77" conference, or show restraint, temporize and hope for the best? The regime's answer thus far appears as ambiguous as the question. There has been considerable harassment of the signatories, but only one has recanted thus far, while others have added their signatures. Four individuals have been arrested. While some have been subsequently released, several may face trial or be expelled. The regime's case against them allegedly is not directly connected with the signing of the manifesto. At the same time, the regime has mounted a major propaganda campaign which claims that the signatories are "foreign agents" and that the movement is supported and initiated by "foreign powers" which are "interfering" in the country's internal affairs.

While the regime's charges are patently false, given the long history of local struggle for civil liberties and human rights, there is little doubt that the movement received considerable support from abroad. Appeals have been sent out—and support received—from the Communist parties of Italy, France, Spain, UK, Sweden and others, as well as from such West European socialist leaders as West Germany's Willy Brandt, Sweden's Olof Palme and Austria's Bruno

Kreisky. What the signatories may not have anticipated is the support from like-minded dissidents from within the communist systems of USSR and Eastern Europe. Nevertheless, the fact remains that the initiative has been seconded—despite the major risks for those voicing their support—by Andrei Sakharov in the U.S.S.R., the twenty-odd members of the Workers Defense Committee in Poland, some thirty intellectuals in Hungary, a handful of dissidents in Yugoslavia, a few—by now mostly expatriated—dissidents in Romania, and, even though indirectly, some hardy dissident souls in Bulgaria.

The "Charter 77" cause thus has found echoes throughout the area and represents the first instance since the Communist regimes came to power that disparate elements in Eastern Europe and the USSR have voiced common dissent with prevailing policies.

Given the prominent attention the dissent has received in the world's press and the criticism voiced by prominent intellectual figures and government officials in the West, the reaction of the East European authorities was a half-hearted mixture of intimidation and restraint, in the apparent hope that the problem will go away.

The years since the last Joint Economic Committee report assessed the situation in Eastern Europe<sup>2</sup> have seen a major expansion in East-West trade.

TABLE 1.—VOLUME OF EAST EUROPE'S TRADE WITH THE WEST  
[Turnover in billions of U.S. dollars]

	1965	1970	1975
Eastern Europe.....	6.6	12.3	35.5
Poland.....	1.1	1.9	9.2
Yugoslavia.....	1.6	3.4	7.9
East Germany.....	1.2	2.5	6.3
Romania.....	.6	1.4	3.9
Czechoslovakia.....	.9	1.6	3.8
Hungary.....	.7	1.2	2.9
Bulgaria.....	.4	.5	1.5

By 1975 the volume of East Europe's trade with the West exceeded \$35 billion being some 70 percent larger than Soviet trade with the West. East European imports were nearly seven times the level registered in 1965 while imports of machinery and equipment registered the largest increase. The most pronounced trade expansion was thus accounted for by imports of technology, representing a reasoned decision that without massive inputs of Western technology the area will not be able to realize its aim of economic growth and better consumer satisfaction. While East European imports boomed, exports continued to lag behind finding little acceptance in Western markets. This forced the importers to rely increasingly on Western credits and East European hard currency indebtedness rose sharply, reaching an estimated \$31.4 billion by the end of 1976.

<sup>2</sup> Reorientation and Commercial Relations of the Economics of Eastern Europe-JEC, August 16, 1974.

TABLE 2.—EAST EUROPE'S HARD CURRENCY DEBT

[In billions of U.S. dollars]

	1975 (estimate)	1976 (estimate)
Eastern Europe.....	24.4	31.4
Poland.....	6.9	10.0
Yugoslavia.....	5.4	6.5
East Germany.....	3.8	4.7
Romania.....	3.0	3.2
Hungary.....	2.1	2.6
Bulgaria.....	1.8	2.3
Czechoslovakia.....	1.5	2.1

By the end of 1976 the accumulated East European hard currency indebtedness was about double the level of its annual exports to the West, ranging from a quadruple and triple of annual exports to the West in the case of Bulgaria and Poland, to somewhat less than one year's level of exports in the case of Czechoslovakia. While thus far the ability of East European countries to borrow did not suffer thanks to prevailing high liquidity among the Western lenders, several regimes—among them Poland, Romania, and Yugoslavia—scaled down the originally planned purchases in the West, maintaining imports at approximately unchanging levels. It would appear safe to conclude that East European ability to earn hard currency will have to improve should East-West trade continue to grow and the hard currency indebtedness stabilize.

The U.S. share of the East-West trade boom remained small—about 7–8 percent of the total, while the U.S. trade surplus exceeded \$1 billion; U.S. banks underwrote about 10 percent of Eastern Europe's debt.

TABLE 3.—VOLUME OF U.S. TRADE WITH EASTERN EUROPE

[Turnover in millions of U.S. dollars]

	1965	1970	1976
Poland.....	101.3	167.9	942.2
Yugoslavia.....	211.0	264.1	684.7

Hungary.....	11.4	34.5	112.1
East Germany.....	19.0	42.6	78.5
Bulgaria.....	5.3	17.7	76.3

Source: U.S. Bureau of Census.

A significant factor bearing on the relatively meager U.S. performance was attributable to restrictions imposed by U.S. legislation. The Jackson/Vanik and Long/Gravel amendments to the Trade Act of 1974 were attacked as discriminatory by the U.S.S.R. and its allies who—claiming interference in their internal affairs—refused to enter into agreements which would have enabled them to obtain the Most Favored Nations (MFN) treatment and made their exports more competitive. As table 3 shows, U.S. trade reached much higher levels

with countries which already have been receiving MFN treatment—like Yugoslavia and Poland; or have been willing—like more independent Romania—to conclude a trade agreement under the Trade Act's terms.

No other East European country has thus far shown willingness to follow in Romania's footsteps, although both Hungary and Bulgaria have made a considerable effort to settle outstanding bilateral issues. Their reluctance to proceed is attributable to the political and economic control Moscow exercises over these countries through party ties, multilateral institutions in the military and economic field (Warsaw Pact and COMECON), and as a major supplier of raw materials and a market for Eastern Europe's substandard manufactures.

As table 4 indicates, the trade of the majority of East European countries is still overwhelmingly oriented toward Moscow and other communist countries.

TABLE 4.—SHARE OF EAST EUROPEAN TRADE WITH COMMUNIST COUNTRIES

	[Percent of turnover]		
	1965	1970	1975
Bulgaria.....	77	78	77
Czechoslovakia.....	73	70	70
Hungary.....	68	65	69
East Germany.....	72	72	67
Poland.....	65	66	50
Romania.....	65	56	50
Yugoslavia.....	35	25	32

While the area's reliance on Moscow is rooted in the similarity of systems, self-serving economic considerations and Moscow's role as the ultimate guarantor of unpopular regimes, the latter—like the populations—chafe under Soviet domination, constantly seeking greater elbow-room in domestic and/or foreign policy. The extent of such strivings ranges from Yugoslavia—which maintains a fully independent posture in domestic and foreign affairs—through Romania and Hungary—where major departures from Moscow's line exist in foreign affairs or domestic policy—to Bulgaria, where policy differences are practically non-existent. An illustrative example is that of Poland, where unorthodox domestic policies (which condone a major role in the country's life for private enterprise in agriculture and the service industries, the toleration of dissident workers and of a powerful Catholic Church) combine with a close support for Moscow's foreign policy and a realistic appreciation by the authorities that Moscow is the ultimate guarantor of their continuation in power.

Throughout the area there is a certain basic similarity of attitudes rooted in the near-identity of institutions and overgrown bureaucracies that control both political and economic decisionmaking.

All policymaking power in Eastern Europe, as in the U.S.S.R., rests with the communist parties whose organizational structure, despite some differences in terminology, is practically identical with that of the U.S.S.R. Through an intricate system of cells reaching down to individual city blocks, factories, and offices the party not only exerts its influence over most of the daily life, but also maintains its hand on the pulse of society. At all administrative levels (state,

regional, district and local) it actually maintains a shadow government which from behind the scene leads ministries, drafts laws, and in effect hands down court sentences long before the responsible legislative, executive or judiciary organs address the subject. In some cases the party men actually hold both positions: behind the scene in the party, and in full public view as the President, the Prime Minister, or the Chairman of the Parliament. Some countries—for example, Romania and Poland—have attempted to streamline the structure by merging a number of party and government bodies below the national level.

In each country the approximately dozen full members and about half-a-dozen candidate members of the Politburo (or Presidium) represent the highest party authority and are the real policymakers in such varied fields as foreign or military affairs, economic matters, cultural policy, et cetera. The somewhat smaller Secretariat supervises the execution of Politburo decisions, directs the party's current work, and controls the movement of members up or down the party ladder. The First (or General) Secretary heads both the Politburo and the Secretariat and is the most powerful man in the party and the country. All Politburo and Secretariat incumbents are also members of the some 100-member-strong Central Committee—a sort of party parliament which by statute is the highest party authority when the party congresses (held every 5 years) are not in session.

In practice, the Central Committee plenums usually serve no other role than to rubberstamp Politburo decisions. However, if factional infighting develops in the party hierarchy, the Central Committee can assume crucial importance in that it decides the political survival or demise of one or the other warring Politburo or Secretariat faction. (For instance, the Czechoslovak Party Central Committee decided in 1968 to oust First Secretary Novotny and to replace him with Dubcek; the 1970 replacement of Gomulka with Gierek in Poland was similarly the result of a Central Committee action.) The statutory responsibility of the Central Committee or of the party congress to elect the Politburo or the Secretariat members has thus at times actually been discharged. For the most part, however, decisions of this type are usually made by the Politburo itself and rubberstamped by the party parliaments.

The Council of Ministers, composed of a prime minister, some half dozen deputy premiers, and 10 to 35 ministers is according to the constitution the "supreme organ of state administration." Actually, it is no more than the executor of party policies and instructions. According to the constitution, the Council of Ministers is appointed or recalled by the national parliament or the state president. In fact, the selection of incumbents is made by the party long before the parliament acts upon them. According to the constitution, the individual ministers "direct" specific branches of state administration, while the Council of Ministers can "rescind an order of regulation" issued by a minister. In practice, the unwieldy Council of Ministers rarely acts as a body, leaving this function to its Presidium (or Bureau) composed of the Prime Minister and his deputies.

The parliaments, known as National or People's Assemblies are for the most part unicameral bodies (in Yugoslavia and Czechoslovakia the parliament has two chambers) composed of some 250 to 400

deputies. The latter are elected usually for a 4- or 5-year term on a single national front slate. The slate includes some independents and puppet party candidates—where such parties exist—but in every instance the communists retain a majority on the slate, despite the fact that the nonparty candidates are handpicked and hardly less reliable than authentic party members. While according to the constitution the parliaments are the “highest organ of state authority,” they are in fact the lowest in terms of political power and, except in Yugoslavia, simply ratify legislation drafted by the party.

The principle of parliamentary representation is carried down the ladder of territorial organization parallel with the party structure. Thus, on the regional, district, and local levels there is a system of local government which is in essence a miniature of parliaments and Councils of Ministers under such names as Peoples Councils, National Committees, and so forth. These are usually elected at the same time as national parliaments.

Each Council or Committee exercises government authority over the area of its responsibility. Lower levels report and are responsible to their immediately superior level and ultimately either to the parliament or to the Council of Ministers.

Under the principle of no separation of powers and despite the constitutional claim that all judges are independent and subject only to the provisions of the law, the judiciary at all echelons in Eastern Europe is nothing more than an extension of the authoritarian party rule.

The purpose of these mechanisms is to provide the regimes with the most varied control over the population which, since the communist takeover, has been an unwilling captive of the system. The institutional framework is designed to provide close supervision of each individual by government and party agencies and is further augmented by an extensive network of secret and regular police, informers, party-dominated mass organizations (trade unions, youth associations, and so forth), and a system of indoctrination by public media and schools.

Yugoslavia, which broke with the Soviet bloc nearly thirty years ago, is a notable exception to this pattern. While it also does not allow opposition parties, it has evolved since 1948 a system of rule which, while institutionally similar to the one described above is significantly more decentralized, permissive, and responsive to public opinion pressure—especially from the half a dozen constituent nationalities. Apart from total rejection of Soviet hegemony and pursuit of a “nonaligned” foreign policy, the most notable Yugoslav departures from the Soviet-type system are the “guiding” rather than “directing” role of the Party; a system of “workers’ management” which gives employees in each enterprise a voice in managerial decisionmaking, including the dismissal or the appointment of a manager; and an economic system which assigns the market forces, profit, and the individual manager a substantially greater degree of influence than anywhere else in Eastern Europe. Another earmark of the system is the markedly greater willingness to experiment with existing institutions and to make frequent changes in the political and economic structure on a trial-and-error basis. Over the years, but especially since Khrushchev’s conciliatory 1955 Belgrade Declaration conceding that there

are "separate roads to socialism," these Yugoslav practices have attracted a number of imitators elsewhere in Eastern Europe (notably in Poland, Czechoslovakia, and Hungary). Most of these, however, proved rather shortlived, once they ran into Moscow's opposition.

The dissent which currently plagues Eastern Europe has made the authorities there realize that a new crisis of confidence in the East-West relationship appears to have arisen and that it could well come to a head at the forthcoming review conference in Belgrade. In approaching that conference the East European regimes face a dilemma. On the one hand, they desire to maximize their access to Western technology, Western credits and markets to promote their economic progress. In this context the maintenance of Western goodwill is a necessity. On the other hand, the dissident demands for a more relaxed, liberal rule at home is perceived as a threat to the system and a demand to relinquish tested methods of rule—at least in the more orthodox countries. The failure to grant at least some of these demands, however, courts an adverse reaction in the West, could upset state-to-state relations with Western countries, and ultimately repel Western economic partners. The reaction to this dilemma is likely to be a major test of the East European regimes' aptitude to govern. The outcome is by no means certain, except that the economic advantages would in all likelihood be secondary should there occur a real threat to the survival of the existing system. In addition, Soviet attitudes are likely to influence strongly all countries except such traditional mavericks as Yugoslavia, Albania, and Romania.

\*A good many people had a hand in getting this paper written. John T. Whitman encouraged and supported the effort and provided valuable criticism of the results. Others who read, criticized, and influenced the paper include Maurice Ernst, Douglas Diamond, Robert Kovach, Joan Zoeter, Hedija Kravalis, and Allen Lenz also made useful comments, though too late to be fully reflected in the text.

For specific contributions I should like to thank in particular Damian Gullo, along with Elizabeth S. Bell, Elaine A. Byers, Doris Pondexter, and Deborah Reed, for developing the Czech and Polish trade statistics used; John Haberstroh and Richard Kraft, for projections of the supply and uses of energy; Kathryn Melson, for extensive work on Soviet trade statistics; William J. Newcomb III, for analysis and projection of East European trade in agricultural commodities, and Donald H. Voss, for compiling revised GNP series. Several others, including M. Anne Ball, Merritt C. Bragdon, and Harold H. Lent, Jr., provided information. Without all this help, the paper as it stands could not have been done. For errors of fact and interpretation, I bear full responsibility.

## SUMMARY

Since 1960 the East European countries, like the U.S.S.R., have been engaged in "peaceful economic competition with the capitalist world." They have kept their economies growing at least as fast as similar Western economies—much faster, according to their claims—without fundamental changes in institutions and policies. This feat has been accomplished at the cost of serious imbalances in their economies—consumer expectations that cannot be met, large inventories of hoarded materials and unsold goods, and import requirements that outrun export capabilities. They cannot go on in this way very much longer without outside help to ease internal strains and trade deficits. Without help, debts to the West are likely to become unmanageable in a few years, forcing a slowdown in economic growth.

The Soviets still supply the greater part of East European imports of fuels, minerals and metals, and materials for light industry. But they are less and less willing to exchange such materials for machinery from Eastern Europe. The area's engineering industries, developed to meet Soviet requirements after World War II, have not kept pace with changing Soviet demand. And the U.S.S.R. itself has found it ever harder to produce enough materials to meet rapidly rising requirements for domestic consumption and export. Therefore, Soviet deliveries to Eastern Europe have grown very slowly since 1970, and have increasingly been contingent on return deliveries of materials. The East Europeans, in turn, have had to look more to the West for crude oil, minerals and metals, and grain, in addition to chemicals and feed supplements, of which the West has long been the major source of supply. Machinery sales get the headlines, but materials have made up the greater part of imports from the West, at present prices more than two-thirds.

While Soviet deliveries of materials have been slowing down, deliveries of machinery have continued to grow apace. The U.S.S.R. supplies a large part of East European imports of plant and equipment for mining, metallurgy, transport, agriculture, and public utilities. Soviet industry has done little, however, to meet the needs of the rapidly growing chemical industries in Eastern Europe or of the revived and expanding light and food industries. To develop these sectors in particular, the East European countries have had to turn to the West for capital equipment, parts, and components.

Since the mid-1960's, while remaining nearly in balance on trade with the Communist world and running surpluses with developing countries, the East European countries generally have run deficits

with the developed West—larger deficits than planned or deficits instead of planned balances or surpluses. As government credits and private bank loans became more readily available, running hard currency deficits became the chief—because the easiest—way of compensating for mischance and miscalculation. It was hardly necessary any longer to revise plans downward.

East European deficits have mounted in recent years in the wake of Western inflation and recession. Terms of trade with developing countries—chiefly OPEC countries—worsened significantly in 1973–74 as a result of huge increases in the price of imported fuels and materials, and those of the GDR and Hungary with the developed West also suffered. In 1975, moreover, the U.S.S.R. took advantage of the same price rises to impose them (with a 3-year lag) on trade with (and within) Eastern Europe; as a result all but Romania and Poland, themselves large exporters of materials, are worse off on balance in intra-CEMA trade. Recession in the West further burdened the East European countries' balance of payments. Although they soon responded by postponing or eliminating some imports, their trade deficits with the developed West shot up rapidly in 1974–75; in 1976, Bulgaria, Hungary, and Romania succeeded in reducing them substantially, but only Romania came close to eliminating its deficit.

Poland and Romania, with the most abundant raw material reserves in Eastern Europe, started out in the best shape to avoid large deficits with the developed West. But they have been correspondingly more ambitious in planning economic growth—Romania since 1959 and Poland since 1970. As a result, their hard currency debt service has risen to about one-half their hard currency exports, or roughly one-third their total hard currency earnings. Poland has gotten a long-term, low-interest loan from West Germany and special pension payments. It has in addition received a sizeable commodity credit from the U.S.S.R. Romania has substantial help from the IMF and the IBRD. With this assistance they can still meet scheduled debt service for the time being.

Bulgaria is in an even more precarious position, with debt service running to over two-thirds its hard currency exports of goods, or one-half its total hard currency earnings. Soviet help presumably has been and will be extended to help Bulgaria meet scheduled payments.

The other three countries—Czechoslovakia, the GDR, and Hungary—have been more careful, in view of their modest export prospects. Their debt service still runs at roughly one-third of hard currency exports of goods, or perhaps one-fifth of total hard currency earnings. None of them has needed special help, and all three will be able to handle debt service for a time.

East European economic plans for 1976–80, though calling for somewhat slower industrial growth than in the last five years, imply continued hard currency deficits for all countries and increased debt burdens for most of them. The countries have not faced up to this problem in their foreign trade plans, although Hungary has come close. Even on favorable assumptions, all are likely to have troublesome hard currency payments problems by the end of the period.

The volume of imports from the West will continue to grow more slowly than in 1971–75, but in most cases more rapidly than planned, probably averaging in the range of 5 percent to 10 percent per year.

Soviet policy continues to minimize increases in exports of materials to Eastern Europe, and all countries will have to increase imports of Western crude oil, minerals and metals, and feed supplements. Imports of most other commodities, including machinery, can be held down through probably not to the extent planned if economic growth is to continue on schedule.

With strong Western recovery, most of the East European countries should be able to expand the volume of hard currency exports considerably faster than imports. If recovery is slow, or temporary, that is probably not feasible. In either case, only Romania has a real chance of meeting export plans for the period—most of the others call for rates of increase two to three times the rates (in real terms) in 1971-75.

On the basis of these estimates, East European indebtedness, estimated at about \$25 billion net for the end of 1976, is likely to rise faster than hard currency earnings. Thus even with strong Western recovery, Bulgaria's debt burden will remain unmanageable without Soviet help; Poland's will probably become unmanageable without more help from some source; the other countries should be able to get by, although Romania will at least need help to recover from the 1977 earthquake. If Western recovery continues to lag for another year or two, all the East European countries may need concessionary loans or refinancing before 1980 unless economic growth is cut back sharply.

The West is likely to face the issue first when Poland asks for balance of payments assistance. That will pose the question of concerted action by major Western creditors to underwrite existing bank credits, control future credits, and stabilize trade. The problems of the other countries as well will have to be faced sooner or later if they are to continue "peaceful economic competition" with the West, one of the conditions of "detente" in Europe.

#### INTRODUCTION

Since 1960 the East European countries have been guided by the Soviet policy of "peaceful economic competition with the capitalist world." The adoption of this aim marked a break with the policies of the late 1940s and 1950s, designed to prepare the Soviet Bloc for an early economic and political crisis in the West. In turning to "peaceful economic competition," the Soviets were taking account of the growing economic and political strength shown by the developed West in the 1950s, which they attributed to rapid introduction of technological change, the "scientific-technical revolution." By following the same course in the U.S.S.R. and Eastern Europe, the leaders hoped to maintain steady, rapid economic growth, gradually strengthening their competitive position in the world. This long-run aim still guides East European economic policy, in spite of recent signs of economic and political weakness in the West.

East European leaders have held to this aim with the help of rapid growth in foreign trade, more rapid than foreseen. Since the mid-1960s the volume of trade has risen as fast as in the developed West; the rate of growth in the volume of trade has averaged more than one and one-half times the rate of increase in GNP. The East European countries have for some years, however, been having

heavier going in trade both with the U.S.S.R. and with the West, which play complementary roles in their trade. The main difficulty is that their manufacturing industries, modernized and greatly expanded, remain uncompetitive for the most part.

The present study traces the development of the increasingly critical trade and payments problems of the East European countries, indicates the likely impact on their economies and foreign trade and suggests the implications for Western policy.

### TRADE WITH THE U.S.S.R.

Soviet economic support has been a necessary condition of maintaining economic growth and political stability in Eastern Europe. During the late 1940s and 1950s, prewar export industries had languished; the new heavy industries developed in their place had little to offer the West. As a result, the East European countries were altogether dependent on the U.S.S.R., which was obliged to go on supplying most of their deficits in basic materials. The Soviets still supply the greater part of their imports of crude oil, coal and coke, crude phosphates, ferrous metals, wood and wood products, and natural textile fibers.

Nevertheless the Soviets recognized from the early 1960s that a large and growing loss was involved in the exchange of Soviet basic materials for East European machinery and equipment. In terms of Soviet (or *a fortiori* East European) relative costs, East European machinery and equipment exports were overvalued. The resulting loss, which Edward A. Hewett estimated at 38 percent of the value of Soviet exports to the area in 1960,<sup>1</sup> could be expected to rise with the rising costs in Soviet extractive industries; costs in the engineering industries, on the other hand, were stable or declining. The trade also worked to the disadvantage of the U.S.S.R. in terms of relative scarcities. Machinery production in Eastern Europe, developed in the postwar period to serve Soviet needs, no longer represented an essential source of supply; on the contrary, the U.S.S.R. could readily expand capacity to meet its own needs for most of the machinery and equipment imported from Eastern Europe. But the supply of basic materials was already a limiting factor in CEMA planning in the early 1960's and clearly was going to become increasingly critical during the decade, restricting Soviet growth and exports to the West.

The U.S.S.R. proposed in the mid-1960s to shift CEMA prices to a basis reflecting costs in major producing countries in the CEMA area, costs that the Soviets were for the first time beginning to reckon. But most East European countries objected so stoutly that the Soviet leadership gave up the proposal. CEMA prices for machinery continued to be high, perhaps reflecting initially high prices offered by Western suppliers and the subsequent price rise on Western markets. But prices of materials in CEMA fell in response to the fall in Western prices. As a result, Soviet terms of trade with Eastern Europe deteriorated significantly in the 1960's. As a partial offset, the U.S.S.R.

<sup>1</sup> Unpublished paper, Edward A. Hewett, "Prices and Resource Allocation in Intra-CEMA trade," cited by Paul Marer, "Soviet Economic Policy in Eastern Europe," Reorientation and Commercial Relations of the Economies of Eastern Europe, printed for the Joint Economic Committee, Washington, D.C., August 16, 1974, pp. 149-150.

in 1966-67 required "investments"—in effect, commodity credits—from Czechoslovakia and the GDR as a condition of their continuing to get Soviet oil.<sup>2</sup>

The main offset, however, stemmed from another bilateral approach, dating from about 1960, when the Soviets began holding back the exchange of materials for East European machinery. Under this approach, deliveries of basic materials have become to an increasing extent contingent on return deliveries of goods desired by the Soviets—raw materials, semimanufactures, foodstuffs, and consumer goods. The Soviet move, very gradual, toward balancing exchanges of "hard goods for hard goods" has had quite differentiated effects. The more industrialized the country, the higher the initial Soviet subsidy, the sharper the decline in the subsidy—and the slower the rise in Soviet deliveries of basic materials. Through the early 1970's the subsidy was still large for East Germany and significant for the other northern countries; Bulgaria and Romania, which at first were providing a subsidy to the Soviets, have been able to reduce it by the same means.

The shifts in machinery trade are illustrated in the accompanying graph, based on Soviet trade statistics, showing the gradual increase in Soviet exports as a percentage of Soviet imports in machinery trade with the more industrialized countries and the reverse in trade with Bulgaria and Romania. The impact of Soviet bargaining on trade in materials is shown in table 1, which indicates how the growth of Soviet deliveries of materials is related to their size and the reverse flow of materials. Increases in Soviet deliveries are also related to the Soviet economic situation, notably in 1971-74, when net deliveries of materials to the area actually declined a little, with a sharp drop in net deliveries to Czechoslovakia and Poland and a leveling off in net deliveries to the GDR. The contrast with the late 1960s is even greater when Soviet terms of trade are taken into account—these worsened only marginally in the early 1970s, as against the substantial deterioration from 1965 to 1970.<sup>3</sup>

<sup>2</sup> See Paul Marer, "Postwar Pricing and Price Patterns in Socialist Foreign Trade (1946-1971)" (IDRC Report 1), International Development Research Center, Indiana University, 1972, especially pp. 24-56. Marer points out (pp. 40-41) that there is no clear case that the East European countries paid higher than going prices in general for Western goods. There is a strong inference, however, that they initially paid much higher prices for machinery. Hungarian price indexes included by Marer (p. 81) show a sharp drop after 1963 in prices of machinery imported from the West, whereas "world market prices" for machinery rose substantially through the decade even after allowance is made for product improvement (pp. 89-90). As he also concludes (p. 58) and as the Hungarian indexes illustrate (p. 80), intra-CEMA prices for machinery held up through the decade.

<sup>3</sup> See Martin J. Kohn, "Developments in Soviet-East European Terms of Trade, 1971-1975," Soviet Economy in a New Perspective, printed for the Joint Economic Committee, Washington, D.C., October 14, 1976, pp. 73-75.

## Imbalances in Soviet-East European Machinery Trade

<sup>1</sup> Trade in CTN 2-8, including nonitemized trade. These groups cover fuels, minerals and metals, chemicals, building materials, live animals, wood, cellulose, paper, textile fibers and textiles, hides and skins, leather, tobacco, technical fats, oil seeds and meal, grain and other food raw materials, and processed food and beverages. The figures are derived from official Soviet trade statistics by subtracting machinery and equipment, itemized consumer goods, and estimated trade in military end items. See appendix A.

Some materials (fuels and foodstuffs) were, so to speak, "harder" goods than others (metals and chemicals) in terms of cost/price relations, changes in relative scarcity, and marketability in the West. The "harder" goods made up a larger part of deliveries of materials by some countries (notably the U.S.S.R., Poland, and Romania) and a smaller part in deliveries by others (notably the GDR). To consider such differences in composition would reinforce the arguments in the accompanying text.

<sup>2</sup> The use of 1970 exchange rates eliminates the effect of dollar devaluation in 1971-73.

As a result of these shifts in the composition of trade, the net cost of the trade to the U.S.S.R. was down to about 25 percent of exports in 1970, according to Hewett's estimate,<sup>4</sup> in spite of the deterioration of Soviet terms of trade. The cost was cut sharply in the early 1970s and has now disappeared as a result of the large increases instituted beginning in 1975 in relative prices for fuels, materials, and foodstuffs. These increases, resulting from a shift to "average world market prices" of 1972-74, imposed some worsening in terms of trade on all East European countries, ranging from perhaps a 20 percent decline in Czechoslovakia's to a very small decline for Romania.<sup>5</sup>

<sup>5</sup> Kohn, *op. cit.*, p. 77.

## TRADE WITH THE WEST

Trade with the West has complemented trade with the U.S.S.R. and within Eastern Europe. In particular the West has supplied modern oil refinery equipment, over two-thirds of the chemical industry equipment, sizeable amounts of electrical and electronic equipment, much of the machinery needed to modernize the neglected light and food industries; major deliveries for equipping the automotive industry; second-hand ships; about one-half the chemicals imported; growing shares of imports of crude oil, ores and metals, and grain; practically all the rising imports of feed supplements; and of course citrus fruits; coffee, and cocoa. This by no means exhaustive list suggests the key role that the West has played in modernizing the East European economies and assuring economic growth. The significance of Western plant and equipment deliveries is generally recognized; but in value terms, imports of Western raw materials and semimanufactures have been consistently greater—at today's prices more than two-thirds of the value of Western deliveries. A significant and growing share is provided by less developed countries.<sup>6</sup>

Reliance on the West has varied widely in the area from country to country. In real terms, well over one-half of Romania's imports have come from the West since 1967, and the share has grown. For Bulgaria, on the other hand, the share has been less than one-third. For the other countries the shares have lately been in the range between one-third and one-half, the share approached by Poland in 1975. Table 2 traces the real growth of imports from the Communist world and the West between 1960 and 1975. Only for Czechoslovakia have imports from the Communist world grown more rapidly than from the West.

TABLE 2.—GROWTH OF EAST EUROPEAN IMPORTS FROM COMMUNIST COUNTRIES AND FROM THE WEST, 1960-75  
[1960 equals 100]

Romania.....	134	240	163	560	248	951

<sup>1</sup> Official East European statistics deflated for price changes. See appendix C.

In the effort to pay for desired—often badly needed—imports from the West, the East European countries have had to rely on exports of the same commodities increasingly desired by the U.S.S.R.—industrial raw materials and semi-manufactures, foodstuffs, and consumer goods. The developing countries, which play an important role in the trade of several countries (the conspicuous exceptions

<sup>6</sup> East European trade data are used in drawing the above conclusions. See Appendix B. The geographical distribution of East European trade is considered here only *ex post*. Much of the unplanned increases in East European imports probably came from the West. See Jozef M. van Brabant, "On the Determination of the Level and Distribution of Planned and Unplanned Trade in a Centrally Planned Economy," *Jahrbuch der Wirtschaft Osteuropas*, Munich/Vienna, Vol. 6, 1975, pp. 317-60.

are the GDR and Poland), have accepted a good deal of machinery on medium- to long-term credits with low interest rates, repayable in kind with crude phosphates, iron ore, copper, cotton, and sometimes oil seeds, fishmeal, and crude oil. Developed Western countries, however, which supply machinery and most of the chemicals, metals, and grain imported from the West, offer thin markets for East European machinery. Even Czechoslovakia and East Germany, the most competitive exporters, have succeeded in raising machinery exports to only a very modest share of total exports to the developed West—13 percent-14 percent in 1974<sup>7</sup>—even with large discounts. Moreover, the East Europeans have faced quantitative restrictions on sales of foodstuffs and agricultural products (especially meat and live animals) and consumer goods, especially in recent years. The GDR with, its privileged access to the West German market—and special advantage in trade with West Berlin—is a partial exception. Otherwise, countries with exportable raw materials and semimanufactures—notably Poland and Romania—have been in the strongest position in developed country markets. It was of course this advantage that enabled Romania to shift such a considerable part of its trade westward.

Price increases for materials on world markets in 1973-74 have magnified the advantages of Poland and Romania in particular, and the disadvantages of the GDR and Hungary. Poland's terms of trade have substantially improved with the developed West (except in 1973); but worsened slightly with developing countries (because of a sharp deterioration in 1973-74). Romania probably did as well, except for a substantial deterioration in terms with developing countries as a result of price increases for oil imports. For Czechoslovakia, the most significant worsening of terms of trade apparently was with the developed West in 1974. Bulgaria may have come out fairly well with the developed West, but terms of trade with the developing countries undoubtedly suffered. For the GDR and Hungary the price changes resulted in substantially worse terms of trade with both developed and developing countries.<sup>8</sup>

Nevertheless, the industrializing countries—Romania, Bulgaria, and recently Poland—have run the largest trade deficits with the West (relative to exports). An appetite for economic growth together with optimism about prospects for earning hard currency has led Ceausescu, Zhivkov (until held back by the Soviets), and finally Gierek to expand imports very rapidly, more rapidly than they could expand exports. To finance the resulting trade deficits had already become a problem for Bulgaria in the mid-1960s, and the Soviets, though ready to help out, also effectively discouraged further heavy reliance on Western imports. Romania, in some embarrassment over payments, sought and received Western (principally West German) refinancing in 1970 and again in 1973,<sup>9</sup> but continued to run large deficits through 1975. Finally, Gierek, who took over at the end of 1970 from the normally cautious Gomulka, has set a new record for East European trade deficits beginning in 1973, and has gotten into the same difficulties. The annual trade deficits with the developed

<sup>7</sup> The shares dropped in the 1970's as a result of major increases in prices of basic materials.

<sup>9</sup> See Melson and Snell, p. 1369-1395.

West are shown in Table 3 for the years 1965-75. The hard currency deficits on current account were generally smaller, notably in the case of the GDR, through the early 1970s. Since then, however, balance of payments deficits have grown even faster than trade deficits as a result of mounting interest payments.

TABLE 3.—EAST EUROPEAN TRADE BALANCES WITH THE DEVELOPED WEST, 1965-75<sup>1</sup>  
[In millions of dollars]

	1965	1966	1967	1968	1969	1970	1971	1972	1973	1974	1975

<sup>1</sup> These data are official figures, adjusted only for GDR trade, to correct for the conversion of intra-German trade into East German mark (VM) from DM at parity. As a result of the treatment of transport costs, Polish deficits are understated and Hungarian deficits overstated.

### DEBTS TO THE WEST

The Western recession, coming after a period of boom, hit East European exports very hard in the latter part of 1974 and in 1975 to the apparent surprise of the planners, leading to greatly increased deficits. Price increases in 1973-74, together with the devaluation of the dollar in 1971 and the further decline in the dollar relative to strong currencies in 1973, also caused an increase in debts expressed in current dollars. Table 4 shows net hard currency indebtedness in 1973-75, probably estimated on the low side. Debts have increased further in 1976. Although hard currency trade deficits of some countries were smaller than in 1975—Romania's was much smaller—interest payments were larger, and earnings from invisibles did not keep pace. All in all, the rise in indebtedness appears to have been more than in 1975, bringing the total to about \$26 billion. Poland's debt, estimated at \$10 billion by the end of the year, rose the most rapidly.

TABLE 4.—ESTIMATED NET HARD CURRENCY INDEBTEDNESS OF THE EAST EUROPEAN COUNTRIES,<sup>1</sup>  
1973-75  
[In billions of dollars]

	1973	1974	1975
Bulgaria.....	0.8	1.2	1.8
Czechoslovakia.....	.8	1.1	1.5
GDR.....	2.1	2.8	3.8
Hungary.....	.9	1.5	2.1
Poland.....	1.9	3.9	6.9
Romania.....	2.0	2.6	3.0
Total.....	8.5	13.1	19.1

<sup>1</sup> Also reflects assets and liabilities on clearing account with the developed West (chiefly between the GDR and the FRG). See Zoeter, pp. 1350-1368.

According to these estimates, Bulgaria and Romania appear to be in the most difficult position, now, as in 1970. Bulgaria, with a debt service over two-thirds its hard currency exports of goods, or fully one-half of total hard currency earnings, can probably count on backing—and pressure to do better—from the U.S.S.R. Romania,

with a debt service approaching one-half the value of hard currency exports—or more than one-third of total hard currency earnings—has received very useful help from the IMF and the IBRD in its capacity as a “developing country.” Both countries have had some financing from the Middle East, and both reportedly renewed requests for West German assistance as well—to no avail—in 1975.

Poland, with a debt service ratio more than the Romanian level, but with greater hard currency earnings from invisibles, would seem to be in a more tenable position. A problem, however, is the sheer size of the Polish debt. Although ample government-guaranteed credits are still available to Poland, the volume of private bank credit, more than half the total debt, is larger than the banking community would wish. Poland, however, has had timely West German help in the form of a government-guaranteed 25-year loan of 1 billion DM (\$425 million) at 2½ percent interest, along with an agreement for pension payments of 1.3 billion DM (\$550 million)<sup>10</sup> over 3 years. The old obligations to the U.S. under Public Law 480, down to \$246 million at the end of 1975, can be stretched out. The extension of a Soviet commodity credit of \$1.3 billion could take the pressure off the Gierek regime for a while. Soviet deliveries of grain and additional raw materials and consumer goods will help Poland to pacify consumers and maintain output without adding to deficits with the West. Such help, even though temporary, should also provide some reassurance to Western bankers.

The other three countries, despite a rapid growth in indebtedness since 1970, do not face awkward problems in the near future. Debt service is roughly one-third of hard currency exports, or perhaps one-fifth of total hard currency earnings. Czechoslovakia, whose chief obligations are short- and medium-term supplier credits, has an excellent position in the Eurocurrency market. The GDR has arranged for the first large project credits with West German government backing. Its credit is rated as good in financial markets. Hungary, the East European pioneer in Western financial markets, is more heavily dependent on bank credit, but the reputation of Hungarian bankers remains solid. All three countries have arranged loans on favorable terms in the last year.

#### ECONOMIC PERFORMANCE AND THE IMPLICATIONS

Since 1960, the less industrialized countries of the area, with their stronger trade position, plus greater labor reserves and growing populations, have generally had the highest growth rates. They have moved some way toward “equalizing” output and consumption per capita within the region, a long-term objective supported by the USSR and endorsed by CEMA. The lower growth rates in the other countries have nevertheless been respectable by West European standards.

Economic growth rates have stabilized since the mid-1960's except for a drop in Bulgaria and a rise in Rumania and Poland, reflecting a slowdown in industry in several countries—all but the GDR and Poland—mostly offset by improved performance in agriculture. In table 5, official rates for “national income” (Net Material Product) are compared with estimates of GNP by Thad P. Alton and his group.<sup>11</sup> The estimates of the Alton group are roughly comparable with Western growth statistics.

<sup>10</sup> At end 1975 exchange rate.

The slowdown in industry is masked by official statistics, as a result of a mounting upward price bias in the deflated series used, which reflect the pricing of new products at inflated values. But Alton's estimates have an opposite bias, resulting from the use of available data in physical terms as a basis for indexes; the selection often has a conservative bias, and data in physical units of course do not reflect model changes and other upgrading of products. On the whole, however, the Alton series are better indicators of trends. They are shown in table 6 along with rates of growth for employment and investment. Romania stands out as the one country in which the growth of employment and investment has been maintained at high rates throughout the 1960's and early 1970's.

The East Europeans seem to have been quite successful since 1965 in substituting capital for labor. The results presumably reflect better management, a better educated labor force, greatly modernized plants and processes, and a better mix and flow of current inputs. Western example has had a pervasive influence and imports from the West have helped a lot, not only in modernizing plant and processes but also in improving the supply of current inputs.

<sup>1</sup> Growth of production as estimated by the Alton group. Other figures are official.

The East European countries have all taken in stride the enormous increase in complexity involved in planning and managing economies in rapid technological change, with increased involvement in foreign trade, while making minimal changes in institutions and doctrines. Planning and administration have evolved, and professional competence has risen steadily, but the characteristic inefficiencies of the system have remained—high material consumption coefficients, inflated inventories, cost overruns and long time-lags in investment, variable quality and unsuitable mix of output. In 1960, hardly anyone expected such great changes with so little basic adaptation. The reformers who felt that the example of the West would open up the societies of the area, transforming them into social democracies, have been disappointed. The “technocrats,” while more numerous than ever, have not acquired the political influence they were expected (by some) to achieve; nor have they made much impression on the characteristic inefficiencies of the system.

Disappointment of official fears and popular expectations of the early 1960's resulted in a general letdown in the area, especially after 1968. The renewal of protests during the last year came as a surprise, not least to the leaders themselves. They are concerned, unavoidably, not so much because they fear that the general dissatisfaction and cynicism could easily be politicized as because they are uncertain whether they can continue to provide the economic growth—and the additional consumer goods and services—essential to the stability of their regimes.

Steady and substantial increases in personal consumption since 1960 have left life still anxious and difficult, but easier and more enjoyable for many. Consumption has increased with output, though more slowly. The increase in consumption, as in output, has been faster in countries with lower initial levels.

How fast the growth has been is hard to say, again, as with output. Official statistics are biased upward by the heavy subsidies given to slow growing types of consumption (basic foods, housing, and public transport) and the no less heavy taxing of many rapidly growing types of consumption (better quality soft goods and durables), although the effect is somewhat offset by rapid growth of consumption of subsidized animal products. Moreover, official price indexes are generally based on a conservative sample of goods and services, largely excluding “new products,” the classification and pricing of which has sometimes been quite inflationary. Without the resources of the official statistical services, it is not practicable to deal with all these problems.

To judge from the Alton GNP measures, shown above in Table 5, the growth of personal consumption would have ranged from something over 2 percent to something over 4 percent per year. Converted to a per capita basis, his average annual rates for GNP for 1961–75 are as follows (percent):

Bulgaria.....	4.7
Czechoslovakia.....	2.6
GDR.....	3.0
Hungary.....	2.8
Poland.....	4.1
Romania.....	4.4

Fixed capital investment, inventories, and, by and large, state consumption increased faster than GNP or consumption. But Alton's estimates have some downward bias, as already noted in connection with Table 5; besides, these countries have run significant current account deficits since the mid-1960's, which helped to finance the growth of consumption, as of investment. With these offsets, one may then guess that the growth of consumption in these countries over the period, measured for comparison with their Western neighbors, ran within one-half a percentage point of the rates shown.

One adjustment that can, and probably should, be made is to raise the rate for Hungary to at least 3.5 percent—i.e., well above that for the GDR—and to drop that for Poland a little. Fairly full official series for personal consumption are available for both Hungary and Poland. As it happens, the Polish series yields exactly the rate shown; and even if reweighted to reduce the bias from subsidies and taxes, the rate would run close to 4 percent.<sup>12</sup> The Hungarian series yields a slightly higher rate than the Polish, but if reweighted the rate would drop more.<sup>13</sup>

Other countries publish much less satisfactory data on personal consumption—less complete and more questionable. From what is available, however, it would seem that the adjusted ranking is correct. That is, the growth of consumption in Czechoslovakia—in 1948 by far the most prosperous country in Central Europe—has been the slowest, though that by no means holds for Slovakia. All the others have shown more rapid growth than the GDR, Hungary by the smallest margin, Poland by rather more—entirely as a result of the spurt since 1970—with Bulgaria showing the fastest rate of growth, significantly faster than Romania's.

Who then is best off today? Travelers have seen in Budapest greater evidence of prosperity than even in Leipzig or Prague. An important point is involved: the Hungarian leadership alone has tried consistently to make more use of prices as a basis for rationing consumer goods, though not housing. In Budapest, as a result, salable goods are available in the shops and all can afford them on occasion. Leaders in other countries have held back, whether out of deference to "socialist" policy—and Soviet practice—or whether to avoid trouble with the workers over price increases. This caution, or inertia, is a weak spot in East European consumer policy, a big factor in shortages of desirable goods—not only meat—weakening the effectiveness of wage incentives and at times threatening popular outcry.

In a way, then, the travelers are right. Nevertheless a rough measure of the goods and services consumed would still show the GDR with the greatest personal consumption per capita, followed by Czechoslovakia, Poland and Hungary, Bulgaria, and Romania, in that order; Table 7 shows estimates of consumption relative to the GDR for all these countries. Except for the GDR and Romania, at the two extremes, the ranges overlap. In general, the differences between

<sup>12</sup> The series used in *Rocznik statystyczny*, 1976, p. 83; total consumption from personal income at 1971 prices, divided by the mid-year population figures on p. 29. The rate of 4.1 percent reflects a flat rate growth from the 1960 to the 1975 level; the trend would yield a slightly lower rate.

<sup>13</sup> *Statistikai évkönyv*, 1975, p. 319; the per capita series at constant (1968?) prices excluding "social benefits in kind."

pairs of countries are smaller than they were 15 years ago—between Czechoslovakia and the GDR and between Bulgaria and Romania the differences have increased. Hungary and Poland have changed places.

TABLE 7.—*Levels of personal consumption in Eastern Europe,<sup>1</sup> 1975*

[GDR = 100]

	<i>Level</i>
Bulgaria -----	65-75
Czechoslovakia -----	80-90
GDR -----	100
Hungary -----	70-80
Poland -----	75-85
Romania -----	40-50

<sup>1</sup> Rounded estimates reflecting data discussed in the text. For the relationships in the early 1960's, see Maurice Ernst, "Postwar Economic Growth in Eastern Europe," *New Directions in the Soviet Economy*, printed for the Joint Economic Committee, 1966, vol. IV, *The World Outside*, pp. 885-89.

#### NOTES

Similar relationships are obtained by the use of the purchasing power parities with West Germany given (for all but Romania) by Statistisches Bundesamt, *Internationaler Vergleich der Preise für die Lebenshaltung, Reihe 10 in Preise/Löhne/Wirtschaftsrechnungen*, and by the DIW for the GDR. All these series are based on direct comparisons at much earlier times, updated by index numbers.

Different relationships are obtained for 1973 by the use of 1975 noncommercial exchange rates used in CEMA. Relative to the GDR, the position of Hungary is better, that of Romania about the same, and that of other countries less good (to about the same extent). See Maria Elisabeth Ruban et al., *Die Entwicklung des Lebensstandards in den osteuropäischen Ländern* (DIW Sonderheft 108), West Berlin, 1975, pp. 16-18, 90-91.

Independent comparisons of purchasing power for these countries (all but Romania) in 1966-67 exhibit much the same relation to the estimates of Statistisches Bundesamt and the noncommercial exchange rates. See Berta Backe-Dietrich, "Die offiziellen Devisenkurse und die Kaufkraft einiger RgW Länderwährungen," *Jahrbuch der Wirtschaft Osteuropas*, vol. 1, Munich/Vienna, 1970, pp. 427-34.

Cf. Austrian estimates of net monthly wages of workers in 1973, showing the same rank order, but of course different relative values. B. Askanas, H. Askanas, F. Levck, *Entwicklung und Niveau der Löhne in den RgW-Ländern. Mit einem Lohnniveauvergleich mit Österreich*, No. 21 in reprint series, Österreichisches Institut für Wirtschaftsforschung, Vienna, 1976.

The East Germans are by far the best off in housing—a benefit conferred by the great outflow of people in the 1950's and the almost static population since then. They and the Czechs share the top position in apparel and in consumer durables (and repair services). The Hungarians and Poles approach them in consumption of food-stuffs. Bulgaria ranks a little below Hungary and Poland in all respects, and Romania ranks well below all other countries.

The East Europeans, although aware of a substantial rise in consumption since 1960, and of persistent national differences, mainly take these for granted. What concerns, sometimes infuriates, them is that after three decades of "socialist" rule, the supply of goods and services is insecure and often substandard, and that some people are much better off than others. Standing in line, waiting years for cars and apartments, searching the shops, bribing the butcher and the repairman are still a way of life. For the many families in which all adults work, often moonlighting as well, there is never enough time. Senior party officials and other privileged people do not face these difficulties; those with generous relatives in the West can avoid some of them; pensioners can hardly make ends meet when they can no longer work.

The regimes acknowledge these complaints, act when necessary to keep things under control, but avoid grappling with the basic issues. The price changes that would help to move the economies toward

equilibrium would be unpopular. If better goods and more services are to be produced, someone will have to be rewarded, perhaps disproportionately. Greater, not less, inequality is likely to result.

Comparisons with the West are part of the East European background, especially in East Germany and Czechoslovakia. Changes in consumption since 1960 reflect the effort of the leaders to satisfy popular desires for a Western style of life, so far as possible. The gap between East and West European living conditions has narrowed since 1960 for the industrializing countries, but rather the reverse for the GDR and Czechoslovakia, judging from comparisons for the 1970's for Poland (with France), Hungary (with the U.S.), Romania (with France), and East Germany (with West Germany).

Poland has done a substantial amount of work on international comparisons since the mid-1960's.<sup>14</sup> A recent series of studies, based on detailed comparisons for Paris and Warsaw, yielded the judgment that in 1972, Polish consumption was 46 percent of the French level (37 percent with zloty weights and 57 percent with franc weights).<sup>15</sup> By category the comparison runs as follows (Polish as percent of French consumption):

Food.....	69
Beverages.....	40
Tobacco.....	98
Apparel.....	45
Lodging.....	35
Hotels, restaurants, and the like.....	53
Utilities.....	52
Hygiene and medical care.....	30
Transport and communications.....	23
Recreation and amusement.....	28
Cultural services.....	70

A very elaborate comparison of Hungarian and U.S. consumption in 1970 forms part of the ambitious IBRD International Comparison Project (Phase One), under the direction of Irving B. Kravis, one of the pioneers in international comparisons after World War II. Via U.S./West German comparisons, Kravis finds Hungary's personal consumption at 54 percent of the West German level, "bridging" at the aggregate level, or about 50 percent bridging at the detailed category level, which somewhat reduces the "transitivity" problem.<sup>16</sup> It should be added, however, that Kravis much prefers comparisons that include education, health, and other welfare services by government, excluded from the personal consumption as defined in the usual Western accounts (U.N. Standard National Accounts, or SNA). On that basis, Hungary's consumption is raised to 62 percent or 63 percent of West Germany's. Much the same shift would occur, of course, in comparisons of other East European countries with Western Europe.

No such large-scale effort lies behind the Romanian/French comparison for 1970. The starting point is offered by an apparently careful comparison of prices in Paris and Bucharest in August 1969, which

<sup>14</sup> See UN, ECE, "Comparison of Level of Consumption in Austria and Poland," Conf. Eur. Stats/WG.22/19, 17 June 1968.

<sup>15</sup> Ewa Cwil, "Spozycie przez ludność oraz ceny artykułów i usług konsumpcyjnych w Polsce i w Francji," *Wiadomości statystyczne*, No. 8, 1976, p. 3. See earlier studies in the same journal, notably one by Eugenia Krzczkowska in No. 8, 1975.

<sup>16</sup> Irving B. Kravis et al., *A System of International Comparisons of Gross Product and Purchasing Power*, Baltimore, 1975, pp. 50-3, 172-3, and 234.

showed 3.23 leu to be worth about 1 French franc (the geometric mean of 3.55/1 with a French market basket and 2.93/1 with a Romanian market basket).<sup>17</sup> This is applied to estimated Romanian personal consumption of 7,800 lei in 1970 (for which more data are available than 1969), a rough estimate obtained in a rather involved way.<sup>18</sup> The very approximate result is that per capita Romanian consumption was about 25 percent of the French level (about 9,500 francs) or by fairly easy transition, 28 percent of West German consumption.<sup>19</sup>

Finally, a tentative estimate may be made for East Germany—that per capita consumption was about 63 percent of the West German level in 1972. This is based on a very careful West German estimate of East German aggregate personal consumption at domestic prices, a quite useful contribution, and a West German estimate of the purchasing power parity between the GDR mark and the DM, obtained by the rather perfunctory continuation of a long series that once was supported by extensive direct comparison.<sup>20</sup>

If one goes back to Maurice Ernst's often cited estimates for 1960,<sup>21</sup> it appears that relative to West Germany, Hungary was at least as well off by the 1970's, Poland somewhat better off, and the GDR somewhat less well off (West German consumption = 100):<sup>22</sup>

	1960	1972
Germany, Democratic Republic of .....	68	63
Hungary .....	49	(1970) 50
Poland .....	42	52

The old and new comparisons may themselves not be altogether comparable, of course. But for what they are worth, they do indicate that the less industrialized countries of Eastern Europe have somewhat lessened the gap with their Western neighbors. It is a very slow process, however, heavily dependent on continued trade deficits with the developed West.

<sup>17</sup> Georges Caranfil, "Le pouvoir d'achat du 'leu' romain," *Revue de l'est*, No. 2, 1970, p. 154.

<sup>18</sup> See Appendix D.

<sup>19</sup> Kravis et al., *op. cit.*, p. 234 shows French personal consumption at 11 percent higher than the West German level in 1970.

<sup>20</sup> Estimated GDR personal consumption per capita in 1972 times the estimated purchasing parity (geometric mean) of the East German mark (M) relative to the DM for a 4-person working class family, divided by per capita purchases of West German private households. A 4-person working class family in the GDR has below average consumption per capita, and the purchasing parity drops sharply with rising incomes. Moreover, the ratio reflects relations at the end of 1972 rather than the average. On both accounts the comparison presumably favors the GDR. The personal consumption figure is estimated by a scholar from Deutsches Institut für Wirtschaftsforschung (DIW) in 1967 marks, converted to a per capita basis and adjusted upward by the official East German purchasing power index to put the underlying 1972 data back into 1972 M. For estimated personal consumption see Herbert Wilkens, *Das Sozialprodukt der Deutschen Demokratischen Republik im Vergleich mit dem der Bundesrepublik* (DIW Sonderheft 115), West Berlin, 1976, p. 175. The purchasing power parity is also a DIW estimate, as given in Peter Mitscherling et al., *System und Entwicklung der DDR—Wirtschaft* (DIW Sonderheft 98), West Berlin, 1974, pp. 245-46. Wilkens himself uses such a purchasing power parity for a conversion for 1967, moving forward the estimate to a range of 66 percent to 73 percent of the West German level in 1974, using alternative assumptions about the reliability of the GDR constant price series. The present calculation follows: 81.6 billion M divided by 17,043 million, times 100.8, times .945 divided by 7,214 DM.

<sup>21</sup> Maurice Ernst, "Postwar Economic Growth in Eastern Europe," *New Directions in the Soviet Economy* printed for the Joint Economic Committee, Washington 1966, Vol. IV, (The World Outside) p. 887.

<sup>22</sup> The Polish/West German relation is inferred from the Polish/French relation. See Kravis, *op. cit.*, p. 234, updated to 1972 by national indexes.

## PLANS FOR 1976-80

In the face of worsening trade prospects the East European leaders still hope to continue economic growth at rates close to the average since 1960. Some are betting heavily on their own efforts and early Western recovery to reduce or eliminate hard currency trade deficits; others expect continued hard currency deficits, but are relying on the West (and, at a pinch, the USSR) to help finance them. The Soviets have urged lower growth rates, but to little effect; they are waiting to see what happens.

The decision to try to maintain earlier growth rates could be explained as the effect of inertia; the plans were drafted before the full impact of Western inflation and recession, and it would have been very awkward to make an abrupt shift in economic policy on short notice. But more than inertia was involved. The East Europeans have reaffirmed earlier policies in the hope that they can be maintained. The alternative, to cut back growth rates quite sharply, would hit at popular expectations in a way that none of the leaders would willingly do. Moreover, the acceptance of a darker view of the short- and medium-term future would involve a new balance of power within the regimes; perhaps in the end, new leaders.

Apart from Bulgaria, the East European countries have planned for lower rates of industrial growth than those achieved in 1971-75, much lower for Poland. To be sure, the drop in rates is a doubtful sign of expectations or intentions. The upward bias in official growth statistics mentioned earlier reflects in part factors (such as overpricing of "new products") not present in the plans. The men that manage the East European economies are aware of the resulting *ex post* bias, indeed count on it to help "overfulfill" the plans, as all countries except Bulgaria did in 1971-75. Nevertheless, all but the GDR and Hungary did choose slightly more modest goals in planning for the present period, as indicated by the following comparison with plans for 1971-75 (annual averages in percent):

	1971-75	1976-80
Bulgaria.....	9.2-9.9	9.2
Czechoslovakia.....	6.0	5.7-6.0
Germany, Democratic Republic of.....	6.0	6.0-6.3
Hungary.....	5.7-6.0	5.9-6.2
Poland.....	8.5	8.2-8.4
Romania.....	11.0-12.0	10.1-11.2

In agriculture, however, all the regimes but Poland and Hungary expect to maintain, perhaps increase, the growth of 1971-75, weather permitting. The average annual grain harvest in the area is scheduled to be somewhat greater than in 1971-75; continued, though slower, growth is projected in the livestock sector. These goals are feasible, given an average run of weather and projected inputs and investment. The net result is that all but Poland hope, with luck, to approach the rates of growth in "national income" achieved in 1971-75; Bulgaria hopes perhaps to approach the higher rates of 1966-70. Comparisons of planned increases in 1976-80 with actual increases in 1971-75 are given in Table 8 for NMP, industry, and agriculture.

TABLE 8.—PLANNED RATES OF GROWTH IN EASTERN EUROPE FOR NMP, INDUSTRY, AND AGRICULTURE IN 1976-80 COMPARED WITH RATES IN 1971-75

	Actual 1971-75			Plan 1976-80		
	NMP	Industry	Agriculture	NMP	Industry	Agriculture
Bulgaria.....	7.9	9.1	3.2	7.7- 8.5	9.2	4.0
Czechoslovakia.....	5.7	6.7	2.7	4.9- 5.2	5.7- 6.0	2.7-2.9
German Democratic Republic.....	5.4	6.4	(2.7)	4.9- 5.4	6.0- 6.3	(4.7)
Hungary.....	6.3	6.5	4.7	5.4- 5.7	5.9- 6.2	3.2-3.4
Poland.....	9.9	11.6	4.9	6.9- 7.2	8.2- 8.4	3.0-3.6
Romania.....	11.3	13.1	4.7	10-11	10.1-11.2	5.1-7.6

A general slowdown in industrial investment is projected, except in the GDR and Romania, on the strength of the large projects already completed and by no means fully exploited, and those still under construction. Industrial employment will grow very slowly, except in Romania, and almost the same increases in labor productivity will have to be attained as in 1971-75. Plans for increased crop yields and greater productivity of livestock call, however, for substantial further investment; agricultural employment will continue to drop. Across the board, so far as one can tell, the plans assume steady increases in labor productivity and sharply increased efficiency in the use of fuels and materials.

At the same time, the leaders are promising a continued rise in consumption. The main attention is given to food, housing, and services. Further increases in meat consumption, if at somewhat lower rates, are featured; other projected improvements in food supply are less talked about. Housing shortages are to be eased, especially in major industrial centers. Encouragement, and some resources, will be provided to handicraft cooperatives to improve services, especially repair services.

These are long-standing priorities. The regimes are not proposing to do much to ease disequilibrium in the consumer market. They seem ready to allow modest wage increases and are hesitant to raise the heavily subsidized prices of food and other necessities. Increases are planned in retail trade, especially of high priced durables, with little prospect of improved mix and quality. In other words, the leaders hope to be able to contain, rather than to reduce, consumer dissatisfaction.

All evidence suggests that planning has gone forward on a wide front and in depth, if on familiar lines. Much of the published discussion relates to ways of reducing imports and expanding exports—in the energy sector, ore mining and metallurgy, chemicals, engineering, and agriculture. Still, one would hardly conclude from all the publicity that the planners and the leaders themselves do not know where the imports are coming from to make it all work.<sup>23</sup>

The difficulties are serious on both fronts—in trade with the “socialist” and with the “capitalist” worlds. In spite of some relaxation in 1975 to cushion the effect of higher prices for materials, the USSR continues to push the exchange of “hard goods for hard goods.” A substantial rise in gross deliveries of materials is in store only for Po-

<sup>23</sup> Compare with following discussion of East European foreign trade plans that of Heinrich Machowski, “Aussenwirtschaftspolitische Ziele der RGW-Ländern,” *Europa-Archiv*, 10 February 1977, pp. 85-93.

land, Romania, and Bulgaria, which can make the required counter-deliveries. These countries, in turn, have little to spare for the others, except in exchange for "hard" goods or currency.

Czechoslovakia, the GDR, and Hungary all expect only a slow increase (up to 3 percent per year) in imports of materials from CEMA. Soviet deliveries of oil are scheduled to rise slowly, and the commitments probably will be met even if there is a shortfall in Soviet oil production. Natural gas deliveries are due to rise substantially. Many other imports, however, already have leveled off or are declining; the first improvement will come in 1979-80, when the payback begins on the large new "investments" in the U.S.S.R.

Trade in machinery, on the other hand, will continue to boom and will evidently provide a sharply rising share of total East European machinery imports. Consumer goods will also bulk larger in trade, especially in exports to the U.S.S.R. Machinery and consumer goods will account for most of the large East European "investment" in Soviet industry, and must be large enough in some cases to offset continued deterioration in terms of trade.

The net inflow of materials from the West, which was expanded in 1971-75 to help compensate for the leveling off or decline in net Soviet deliveries, cannot be increased at such rates in coming years. Even with rapid increases in exports of manufactures to the West, there would be a major—and in some cases, unacceptable—rise in hard currency debt. Hungary projects a considerable growth in the volume of imports from the West, more rapid even than in 1971-75. The other countries project lower rates of growth—or no growth—in imports from the West, and Poland and Romania are significantly increasing their dependence on the Communist world. The volume of exports to the West, on the other hand, is to grow faster than ever before, except in the case of Romania; for Poland at twice the rate of 1971-75.

Not surprisingly, machinery purchases are to decline as a share of imports from the West; even Hungary, with the highest planned rate of growth for imports from the developed West, projects at best a small increase for machinery.<sup>24</sup> The other countries plan little or no increase or a decline in the volume of machinery imports from the West. On the other hand, machinery is to lead growth in exports to the West. Much the same pattern is probably to be found in projected trade in consumer goods. An effort to maximize the net inflow of materials is an essential feature of the larger effort to reconcile the goals for economic growth with balance of payments constraints. It dictates the redoubled emphasis on trade with developing countries, which offer the best market for manufactures, as well as increased reliance on payback in manufactures when buying machinery from developed countries.

Estimates of the rates of increase projected by the East European countries in trade with the Communist world and with the West are given in Table 9. These figures reflect published information on increases in constant prices, together with inferences where data have not been given. Published figures showing much higher increases

<sup>24</sup> As indicated by Foreign Trade Minister Jozsef Biro, in a lecture in Vienna in mid-September 1976. "Business Eastern Europe," October 1, 1976, p. 309. The total projected, almost \$3 billion in 1976-80, compares with \$0.6 billion (CTN 1) or \$.55 billion (SITC 7) in 1975.

in trade overall, with the Communist world, or with the CEMA area allow for anticipated price increases, at least with CEMA, during the period. In some cases, base year figures referred to may be expected or planned, not final, results for 1975 (or 1971-75). The price basis is generally not specified: a 1974 price basis is often used in trade with the U.S.S.R.<sup>25</sup>

\* Developed countries only.

### PROJECTED BALANCE OF PAYMENTS WITH COMMUNIST WORLD

The balance of payments implications are suggested by cumulative trade balances calculated from the projected increases. The cumulative balances for trade with the Communist world are shown in Table 10. They do not, of course, reflect all transactions. In particular, the surpluses probably are overstated because of the exclusion from trade projections (and trade agreements) of military end items, which are, however, included in the base year figures for 1975.

TABLE 10.—CUMULATIVE BALANCES ON PLANNED TRADE OF THE EAST EUROPEAN COUNTRIES WITH THE COMMUNIST WORLD,<sup>1</sup> 1976-80

[In billions of dollars]

	Exports	Imports	Balance
Bulgaria.....	24.1	23.2	+0.9

<sup>1</sup> Based on CEMA trade statistics for 1975 and planned trade increases shown in table 9, above, projected on a straight line basis.

With allowance for such errors and omissions, the cumulative balances in Table 10 should provide a useful view of scheduled balances with the Communist countries. The overall export surplus of Eastern Europe—\$6.8 billion—\$7.3 billion—is a little smaller than the independently calculated imports surplus of the U.S.S.R. with the CEMA area during the period, about \$8.2 billion.<sup>26</sup>

<sup>25</sup> For these estimates, see appendix E.

<sup>26</sup> See appendix F.

The East European surplus is explained mainly by participation in joint projects in the USSR; the probable exclusion from the balances, as noted above, of military end items, on which the USSR runs a substantial export surplus; and the projection of some East European net loss on terms of trade with the USSR over the period.

The gross amount of East European participation in Soviet projects was put at \$4.6 billion (3.4 billion rubles, probably at 1975 prices).<sup>27</sup> But this amount includes some investment in labor and hard currency; moreover, the payback in commodities (oil, natural gas, asbestos, iron ore, ferroalloys, phosphate fertilizers, and cellulose), which is to run 11 years or more, will begin in 1979-80.<sup>28</sup> As a further offset the U.S.S.R. will be participating in joint projects in Eastern Europe with a total CEMA contribution of \$3.3 billion (2.5 billion rubles).<sup>29</sup> Accordingly, the net balance of payments effect of joint projects was probably projected at less than \$3 billion.

Net Soviet exports of military end items could easily run \$6 billion or more in 1976-80.<sup>30</sup> Some of the trade projections in table 9 may take such deliveries into account, and it is in any case quite uncertain what effect projections of military trade had on the trade projections.

The worsening of East European terms of trade could have been taken into account to the extent of over \$2 billion, mainly at the cost of Czechoslovakia, the GDR, and Hungary.

Finally, it is reasonable to suppose that the East European countries were expected to run some net surplus on invisibles, in spite of a probable deficit on transport. Payback on earlier projects and Soviet deliveries in consideration of goods and services provided to Soviet forces in Eastern Europe would be two sizable items.

The division of the overall surplus among the East European countries raises various questions, partly because of a lack of information on their participation in one another's joint projects. Bulgaria's surplus of \$0.9 billion is about the same as its projected participation in joint projects.<sup>31</sup> The GDR's \$3.3 billion is larger than the \$2.4 billion (8 billion Valuta Mark)<sup>32</sup> to be put into projects in other CEMA countries, mainly of course the U.S.S.R., but it may not be large enough. The GDR still has a net deficit on transport, chiefly resulting from payments for transit across Poland and for maritime services, although it has been reduced by earnings from other East European countries. GDR terms of trade with CEMA will also worsen during the period. Earnings from services to Soviet forces in the GDR now roughly offset the value of Soviet arms deliveries.

Poland's \$3.3 billion surplus, on the other hand, seems large, especially in view of substantial Polish net earnings on invisibles. Planned net participation in Soviet and East European projects is not known; judging from Poland's share of the projected payback it would be less than \$2 billion. Poland does, however, run a considerable deficit on military account, mainly with the U.S.S.R., and that may help to account for the projected surplus.

<sup>27</sup> See Appendix F.

<sup>28</sup> Sometimes earlier. For example, Soviet deliveries of oil to Poland of 1 million tons a year for help in building a pipeline from Byelorossiya to Lithuania are to begin in 1977.

<sup>29</sup> V. Karpich, "Proizvodstvenoto sutrudnichestvo mezhdu stranite ot SIV—osnova za progresivnoto razvitiie na tehniya stokoobmen." *Vunshna turgoiia*, No. 9, 1976, p. 10.

<sup>30</sup> Here and below, see Appendix F.

<sup>31</sup> FBIS "Daily Report," Eastern Europe, January 5, 1976, p. C1.

<sup>32</sup> *Neues Deutschland*, December 17, 1976, p. 3. Earlier given as 7 billion-8 billion VM.

The \$0.3 billion surplus for Czechoslovakia, on the other hand, seems low, given participation in CEMA projects of \$2.1 billion, or somewhat less than the figure for the GDR.<sup>33</sup> Moreover, Czechoslovakia appears to run a hefty deficit on military end items with the U.S.S.R. and a substantial deficit on transport. At 1974 prices Czechoslovakia was in fact expected to run a surplus of more than 1 billion rubles, but the price changes in 1975 almost eliminated it. Part of the explanation is the payback from contributions to Soviet projects in earlier periods;<sup>34</sup> moreover, the section of the natural gas pipeline built in Czechoslovakia presumably counts as part of its contribution to joint projects.

The unique deficit shown for Hungary raises a question. Like Czechoslovakia, Hungary is making a significant "investment" in the U.S.S.R., though doubtless a smaller one; has a net deficit on invisibles; and is a net importer of military end items. Moreover, terms of trade with CEMA, mainly with the U.S.S.R., will deteriorate by 9 percent over the period, according to Hungarian estimates. Thus a substantial offset of some kind is implied. Part could come from surpluses earned in 1972-74. Some of the offset is doubtless in the form of Soviet and East European participation in projects in Hungary.<sup>35</sup>

Romania's estimated balance is a sign of its increased involvement in CEMA. The balance seems large enough to provide for a modest commodity credit to be "invested" (net) in the U.S.S.R., some repayments to the PRC, and small imports of arms.

#### PROJECTED BALANCE OF TRADE WITH THE WEST

The cumulative balances with the West, shown in Table 11, reflect the striking differences in outlook and policy already mentioned. The deficit projected by Hungary, at most well above the hard currency indebtedness at the end of 1975, comes close to reflecting the import requirements and export capabilities implied in the economic plans. The balance for Bulgaria is unknown, though substantial deficits have probably been projected. Preliminary versions of the Polish trade plans went as far as Hungary's recognizing that the minimum likely growth of imports (4 percent to 5 percent per year) and the maximum export growth (15 percent per year) would still result in a cumulative trade deficit with the West nearly as large as 1975 hard currency debts; other variants projected much larger deficits. The latest

<sup>33</sup> According to a statement of spring 1976, 13 percent of the increase in investment, domestic and foreign, in 1976-80 over 1971-75 was to be accounted for by contributions to joint projects. *Rude pravo*, 14 April, 1976, p. 4. According to the directives for 1976-80, domestic investment was to rise by 194 billion crowns (from 606 billion in 1971-75 to 800 billion in 1980), *Rude pravo*, 21 April, 1976, special supplement. The Czechs normally convert amounts in foreign prices into domestic prices to reflect "internal reproduction price equivalents," or at a rate of about 17.5 crowns = 1 ruble. The rate in 1967 was 18/1; from then till 1974 it dropped only 0.7%. It probably dropped a little more in 1975. (For the 1967 rates, see Miroslava Koudełka, Dušan Libnar, Miroslav Havel, "Peněžní vstahy v ČSSR," enclosure to *Hospodářské noviny*, No. 47, 6 December, 1968, p. 6. For changes from 1967 to 1974, see Zdeněk Orlicek, "30 let československého zahraničního obchodu," *Zahraníční obchod*, No. 5, 1975, p. 5.)

Investment in the U.S.S.R. in 1971-75 was 350 million rubles (see note 34, below), or 6 billion crowns. Thus the total increment in investment in 1976-80 would be about 216 billion crowns (194 - 6 + 28), and the participation in CEMA projects in 1976-80 would be 28 billion crowns, or 1.6 billion rubles. Of this, participation in projects in the U.S.S.R. accounts for 1 billion rubles. See František Marš, "Vzájemný obchod mezi ČSSR a SSSR a realizace plánu integračních opatření," *Zahraníční obchod*, No. 11-12, 1976, p. 2.

<sup>34</sup> In 1971-75 the Czech contribution was 350 million rubles, Frantisek Mares, *loc. cit.* This is probably additional to the 500 million rubles agreed on in 1966, for which payback was to be made in 1975-84.

<sup>35</sup> *Vilagazdašág*, April 3, 1976, p. 1. There is no question but that Hungary projected an import surplus with Communist countries. At 1974 prices the deficit was only 0.7 billion rubles (imports of 15.6 billion rubles less exports of 14.9 billion rubles). *Ibid.*

draft plan; however, projects a cumulative deficit only just one-third the 1975 debt; the change presumably was made as a result of Soviet urging and promises. The GDR has projected a relatively larger deficit. On the basis of the slow growth projected for imports (2.9 percent to 3.4 percent per year) and the rapid growth projected for exports (10 percent to 10.7 percent per year), the GDR would run a cumulative deficit from over one-half to nearly three-fourths of the end-of-year indebtedness in 1975.

TABLE 11.—CUMULATIVE BALANCES ON PLANNED TRADE OF THE EAST EUROPEAN COUNTRIES WITH THE WEST,<sup>1</sup> 1976-80

[In billions of dollars]

	Exports	Imports	Balance
Bulgaria.....	NA	NA	NA
Czechoslovakia.....	15.4	14.9	+0.5
German Democratic Republic.....	18.2-18.5	20.6-20.9	-2.1--2.7
Hungary.....	10-11.0	12.8-13.0	-1.8--3.0
Poland.....	31.5	34.0	-2.5
Romania (developed countries only).....	11.4	11.3	+0.1
Total (excluding Bulgaria).....	86.5-87.8		-5.8--7.6

<sup>1</sup> Based on CEMA trade statistics for 1975, adjusted for the German Democratic Republic, and planned trade increases shown in table 9, above projected on a straight line basis. An adjustment of German Democratic Republic data is made to correct for German Democratic Republic use of a special rate for converting trade with the Federal Republic of Germany. Uncertainty exists in some cases about the appropriate rates for converting East European foreign trade statistics into dollars.

The other two countries have evidently projected trade with the West to meet predetermined balance of payments constraints. Czechoslovakia projects a small surplus with the West for the period as a whole. It is quite unlikely that the planners have succeeded in reconciling the trade projections with the economic growth plans, although they have set ambitious goals for "saving" fuels and materials. Romania, which projects a balanced trade with the developed West, as well as a surplus with developing countries, is surely in much the same position. If Western market conditions are favorable, the Romanians might run trade surpluses in good agricultural years, something they did not succeed in doing even in 1971-73, but hardly a cumulative balance on trade with the developed West for the whole period 1976-80, especially if rapid economic growth is to continue.

#### HARD CURRENCY DEBT PROJECTIONS

The projections of indebtedness associated with the trade plans can be estimated, though very roughly, by allowing for soft currency (clearing) trade and invisibles. Trade surpluses were undoubtedly projected on clearing account (mainly with LDCs), those of Czechoslovakia and Romania being the largest. Moreover, hard currency surpluses were projected on transport and tourism together and on transfers. These would be sizeable for Poland and for the GDR (as a result of transactions with West Germany) and significant for the other countries. Past experience suggests that the net effect would be to make Romania's surplus on trade and services (excluding interest) in hard currency substantially less than the projected trade surplus overall with the West; to turn Czechoslovakia's trade surplus into a

deficit; and to make the GDR's deficit substantially smaller and Hungary's and Poland's deficits significantly larger than the respective trade deficits with the West.

The countries that project substantial cumulative trade deficits with the West—Hungary, Poland, and the GDR—must have projected large increases in hard currency debts by 1980, allowing for these considerations and projected interest payments. The Hungarian debt in 1980 would be 2½–4 times the 1975 level; Poland's projected debt would be more than double that in 1975, and the GDR's would approach twice the 1975 level.

A doubling of the Polish debt, accompanied by the comparable rise planned in exports, would imply a fairly small rise in the debt burden, if it is assumed that the hard currency earnings remain in about the same proportion to exports to the West. For Hungary and the GDR, however, the projected increases in the debt burden must present a disquieting prospect.

Czechoslovakia and Romania have evidently projected very manageable debts—that is the point of the trade projections. The implied Czech debt would rise slowly, along with exports. The Romanian debt would rise more slowly than exports. The Romanians indeed claimed that under the plan they would bring trade and payments into balance, “generally” liquidate foreign debts, and create a reserve of foreign exchange.<sup>36</sup> From earlier statement “generally” may be glossed as meaning “except for some long-term credits.” Even so, this claim implies the netting of hard currency liabilities against much larger projected assets on clearing account (and from compensation deals) with developing countries.

The Soviets unquestionably have been disturbed by Eastern Europe's balance of payments problems, whether acknowledged or ignored, implicit in the planned rates of economic growth. Soviet criticism presumably accounted for a reduction of Bulgaria's goals to the lower limits of the range indicated in the plan directives. Otherwise there has been little observable effect. Even the goals of the revised Polish draft plan announced in December 1976 are unchanged for industry and NMP. Some changes were made; the goals were upped for agriculture, and shifts in sector and branch plans are to yield more for the consumer and for exports, presumably with smaller requirements. The latest Romanian plan of July 1976 is even more ambitious than the draft directive publicized in 1974, though slightly less so in some respect than an intermediate version of February 1976.

It is surely obvious to the Soviets, as to the East European planners and perhaps the leaders, that something will have to give, except in the special case of Hungary. What has led the Soviet leadership to acquiesce in the plans is perhaps a hope of large government-guaranteed credits from the West on concessionary terms, to provide the time to develop export industries and markets in the West—and the time to reduce dependence on imports of Western machinery and equipment.

<sup>36</sup> Mihai Păraluta, “Cincinalul 1976–1980, cincinalul revoluției tehnico-stiințifice. Sarcinile întreprinderilor și organizațiilor de partid din industrie, . . .” *Revista Economica*, No. 5, 1976, p. 18.

The USSR evidently must help out when urgently necessary to preserve these options, as it already may have done in 1976. Apart from continued support for Bulgaria, direct Soviet aid is not likely to take the form of hard currency, but rather of commodity credits. Poland has been assured of aid—the press report of a 1 billion rouble (\$1.3 billion) credit, as already noted, involves (supplementary) Soviet deliveries of barley, raw materials, consumer goods, and machinery “on favorable terms.” Already in 1976, the USSR seems to have given some help to Poland and the GDR, to judge from the Soviet trade surpluses of over \$350 million and about \$600 million, respectively, with the two countries. Other countries may seek, or be offered, Soviet help—even Romania, in view of the March 1977 earthquake.

### TRADE PROSPECTS

How much help the East European countries may need—Soviet help in the short run, Western help in the longer run—is far from certain. At a minimum, it is likely to be greater than suggested by the trade projections for 1976–80. Obviously a great deal depends on the timing and strength of an upturn in the West, which is necessary if East European exports are to rise. For a time, imports from the West can be cut back, as they were, in most cases, in 1976. Over several years, however, imports must again rise if the pace of economic growth is to be maintained. Machinery imports alone can be reduced for a few years with little overall effect on current output and consumption; agricultural imports can be cut if Eastern Europe has a bumper crop, especially if the Soviets help out more and Hungary is willing to sell grain on favorable terms. For other commodities, however, the East Europeans have little choice but to increase imports from the West, once they have run down inventories—as some of them already did in 1976.

Beyond doubt the volume of East European imports from the West will grow less rapidly than in 1971–75 or 1966–70, when the average rate of growth was about 12 percent; at most the growth rate might approach the 10 percent average in 1961–65. Table 12 projects total East European imports from the West, together with hard currency imports; the implied rate of growth (straight line) ranges from 5 percent—10 percent.<sup>37</sup> This is the estimated range within which the growth of imports would probably fall if the East European countries are to continue with planned economic growth. Most, perhaps all, countries’ imports would have to fall within this range. Those with more rapid economic growth—Romania, Bulgaria, and Poland—are due to get the biggest increases in Soviet deliveries, and thus can do with about the same growth of imports from the West as the other countries.

<sup>37</sup> A Polish expert on trade projections, Aleksander Czepurko, has projected an average increase of 7.6 percent per year in East European imports from “developed capitalist countries” in 1976–80, on the basis of trends in 1955–74. Aleksander Czepurko, *East-West Trade Prospects up to 1980* (Forschungsbericht No. 31, Wiener Institut für Internationale Wirtschaftsvergleiche), Vienna, December 1975, especially pp. 42 ff.

TABLE 12.—TENTATIVE PROJECTION OF EAST EUROPEAN IMPORTS FROM THE WEST IN 1980 COMPARED WITH 1975<sup>1</sup>

[In billions of dollars]

<sup>1</sup> Projections made on the basis of considerations discussed in the text.

The rise in machinery imports is allowed to range between zero growth and the average growth rate for all other commodities. Machinery imports could be kept, as planned, at about the 1975 level with little effect on economic growth rates through 1980, for reasons already noted—cuts in the growth of industrial development, lag between imports of plant and equipment and capacity production, and the continued rapid expansion of engineering output and trade in the CEMA countries. On the other hand, a leveling off—or drop—in machinery and equipment imports from the West would make for a greater lag in technology in the 1980s, something the East European countries would like to avoid insofar as they can afford to. In any case, the volume of machinery imports is not likely to double as in 1971-75, but if the countries are able to continue, as assumed, with their economic plans, they are likely to be able to increase machinery imports in a modest way, even though that is not provided for in their plans.

Goals for expanding crude oil imports from the West in 1976-80 have been greatly reduced. In the early stages, the East European plans implied imports of over 50 million tons from the West—almost all from OPEC countries—in 1980, or more than four times the 1975 level of less than 12 million tons. But projected uses for energy have been substantially cut back, while planned domestic production has been upped, with the entire difference reflected in oil imports from the West. The later plans imply a rise of these imports to only about 24 million tons, or less than one-half the original goal. Of this amount nearly one-half, about 11 million tons, is for Romania.<sup>38</sup>

A major reason for sharp cutbacks in oil imports has been the difficulty of arranging for continued—much less expanded—deliveries on clearing or compensation. In the late 1960s and early 1970s, the Middle East countries had “surplus” oil to sell to Eastern Europe on these terms. But it is doubtful that as much as one-half of the oil imported in 1975 was on clearing, and the share is certain to fall; even the amount is likely to decline as earlier agreements run out.

<sup>38</sup> See Haberstroh, pp. 379-395.

Accordingly, hard currency purchases in 1980 are projected at 18 million to 20 million tons, as against perhaps 6 million tons in 1975; at recent prices, a rise from \$0.5 billion in 1975 to \$1.6 billion-\$1.8 billion by 1980.

Imports of minerals and metals from the West are likely to increase steadily and rapidly. For some years, at least, output in the CEMA countries is not likely to keep pace with requirements for domestic users and for the export of metals and metal products to the West. The growth of 1971-75, when the volume of imports more than doubled, is not likely to be repeated, but metals are likely to lead all other imports in growth.

The increases in the area's chemical production during the last ten years and the further rise of 40-60 percent or more projected for 1976-80 should bring the East Europeans much closer to self-sufficiency in chemical products, including fertilizers, pesticides, synthetics, and plastics, even allowing for greatly increased deliveries to the U.S.S.R. East-West trade in chemicals will show healthy growth, but the East European import surplus will continue to drop. The rate of growth of East European imports had already declined to only about 6 percent per year—in real terms—in 1971-74, and imports leveled off in 1975. Growth in 1976-80 should run less than 5 percent per year.

East European reliance on Western grain imports is likely to increase from about 50 percent of gross imports in 1971-75, which averaged about 9.5 million tons a year, to almost 60 percent in 1976-80, when imports are expected to average a little higher. Over the period, however, the amounts should average below imports from the West in 1975, and below the probable peak level in 1976-77. Soviet deliveries were suspended from August 1975 through October 1976, and only modest amounts have been pledged so far for 1977 out of a record crop. The cutoff in Soviet deliveries, together with poor harvests, raised Western deliveries in 1975 to almost 6.4 million tons, and they are likely to average above 7 million tons in 1976-77. Thereafter imports from the West should drop, though remaining substantial. Even with the normal range of weather during the rest of the 1970's, Poland, East Germany, and Czechoslovakia, which usually account for 85 percent of the area's grain imports, will do well to raise average output of feedstuffs to 10 percent above the 1971-75 level. Continued, but slower growth is projected for livestock herds in these countries. Planned rapid increases in meat consumption are to be met in large part by increasing animal productivity, mainly by an improvement of feeding practices, with the help of heavy investment in large-scale enterprises. Output of feedstuffs in the southern countries should rise faster than in the north, and except in poor harvest years, the southern countries should remain net grain exporters. Only Hungary, however, is likely to increase exports to the northern countries.

Soviet deliveries are not expected to exceed 3 million to 4 million tons a year and may run lower. The Soviet Union could meet a large share of Eastern Europe's needs for grain, even during years of exceptionally poor harvests in Eastern Europe, as it did through the early 1960's, but is apparently unwilling to do so. Thus Poland and East

Germany, the main importers of Western grain, turned to the United States in search of long-term agreements guaranteeing access to the U.S. market, the main source of grain for Eastern Europe. Poland has renewed such an agreement with Canada, and East Germany has discussed the possibility with Argentina. Polish and East German imports will account for most of the 6 million tons a year, more or less, projected as the average import from the West in 1976-80.

Imports of feed supplements—oil seeds and meal together with fishmeal—should rise more slowly as East European feeding practices approach Western standards. In 1971-75, imports of these commodities more than tripled; U.S. soybean meal (including transshipments) is the largest single source, accounting for about one-third. Developing countries account for most of the rest, getting hard currency for a large part of it. Further increases in production of feed supplements are planned in the area, notably by Poland, but Western deliveries will remain a major source. Although USDA expected little increase in 1976, substantial increases in imports are likely for later years.

"All others goods," foodstuffs and products of or inputs into the light and food industries, are projected simply as rising with other imports of materials. Roughly two-thirds of East European imports in these categories has come from the West, and the share is likely to rise. The more industrialized countries of the area, the main importers, need Western products to fulfill commitments to consumers and to meet export targets. In years of poor harvests or of political troubles, imports in these categories are likely to jump; otherwise, when hard currency problems get worse, they are likely to drop. Accordingly, projections of imports of these products are very tentative.

In 1976, only two of the six East European countries dropped imports below the 1975 level—at current prices. Import prices dropped by several percent (depending on the country); at constant prices hard currency imports were up except in Bulgaria.

Only Czechoslovakia and the GDR showed increases, in both cases at only a little above the planned rate for 1976-80.<sup>39</sup> These results were achieved in great part by extraordinary measures to compel the drawing down of inventories of materials. Over the 5-year period, it is hard to see how any of the countries can hold imports within the limits indicated by the projections, if economic growth is to continue according to plan. Hungary alone might stay close to the planned 7 percent increase; the other countries will have to move up into the same range, or else cut back growth rates for industry.

On the export side, even tentative estimates are impossible. In the case of Romania the projected growth of exports to the West is well below,<sup>40</sup> and for the GDR only slightly above, the actual growth of the volume of exports in 1971-75. For Bulgaria, the projected rate is doubtless more than double the 1971-75 rate; for the three other countries it ranges from nearly double (Poland), to over 3 times (Czechoslovakia and Hungary) the rate of real growth in 1971-75, as shown in the following tabulation (annual percent increase):

<sup>39</sup> At constant prices, of course, considerably above planned rates.

<sup>40</sup> For the developed countries only.

	Average 1971-75 actual	1976-80 plan
Bulgaria.....	5	NA
Czechoslovakia.....	2-3	9.0
GDR.....	8-9	10.0-10.7
Hungary.....	3	9.9-(13.2)
Poland.....	7.4	14.5
Romania <sup>1</sup> .....	11-12	7.5

<sup>1</sup> Developed West only

With at least as rapid a growth of the volume of Western trade as in 1971-75—an average rate of growth of 8 percent to 9 percent per year—the GDR might come close to the planned growth of exports to the West thanks to its special access to the West German market, and Romania might exceed the plan, in spite of the losses from the 1977 earthquake. It seems doubtful that the other countries would achieve the growth projected, although they should be able to do better than in 1971-75. Poland, in particular, would be likely under these circumstances to exceed a 10 percent rate of growth, and might show the fastest growth of all, given a strong market for coal, sulfur, chemicals, metal products, and foodstuffs. Continued inflation would benefit chiefly Poland and Romania.<sup>41</sup>

The above estimates make some allowance for the extremely rapid rise in machinery and equipment exports projected in the plans of most, perhaps all, these countries. They may well succeed in expanding deliveries to developing countries very substantially, with a rising payback in materials and consumer goods. The rapid increases proposed also in machinery exports to developed countries are less certain, in spite of sizeable increases in 1971-75. In any case machinery and equipment will not bulk large in exports, accounting for at most 20 percent of the area's exports to developed countries in 1980. Apart from numerous cooperative ventures, none of the countries has concentrated on meeting Western market requirements, and most sales will continue to represent a spinoff of research and development pushed to meet requirements at home and in the other CEMA economies. The most salable items may sometimes be preempted by the U.S.S.R. The intense competition on Western markets in recent years is likely to continue, making it hard for the East European countries to hold the markets they have acquired since the mid-1960's.

Thus East European exports will continue to depend heavily on sales of chemicals, metal products, consumer goods, and foodstuffs. In chemicals and metals, too, the East European countries face heavy competition, which will ease only after Western recovery has continued for a year or two. World capacity has been built up greatly since the mid-1960's, and is at present well in excess of demand; East European sales apparently lagged in 1976, and the outlook is not encouraging for 1977. In consumer goods and foodstuffs, competition is also very keen, and West European countries are not likely to relax restrictions on imports from the East until demand has strengthened.

<sup>41</sup> Czepurko, *loc. cit.* projects the following average annual rates for exports in 1976-80 to the developed West, based on the trend in 1955-74: Bulgaria, 27 percent; Czechoslovakia, 6.8 percent; GDR, 7.3 percent; Hungary, 8.4 percent; Poland, 6.8 percent. No figure is given for Romania.

Preliminary results for 1976 indicate that—at current prices, down by several percent from the 1975 level—Romania (with a 18-percent increase in exports to the developed West) in fact exceeded the planned rate, the GDR (with a 10 percent increase) approached the planned rate, and Poland (with a 8-percent increase) fell well below plan. Hungary did better than expected with an above-plan 15 percent increase in exports to the West; and the increase in Bulgaria's exports (18 percent) probably was in the planned range. Czechoslovakia, showed an 8 percent increase, or more than expected.

It is very doubtful that the East European countries as a group can match in later years the achievement in 1976. It will be harder to hold down imports and push exports than in 1976, coming after a year of peak imports and disappointing exports. Exports—except perhaps in Romania—should fall below plan, and imports—except in Hungary—should run above plan. Therefore it seems likely that the balance of payments prospects of all or most of the East European countries are less favorable than projected. Poland will surely need substantial additional relief in order to finance large continued deficits, unless Western demand picks up very sharply in 1977. The other countries can probably manage for another year or two without major relief—assuming that Bulgaria gets continued Soviet help—but if Western recovery is still lagging in 1978, they too could be looking for some help from West Germany.

#### EAST EUROPEAN DEBTS AND WESTERN POLICY

The developed West thus faces in Eastern Europe problems bearing comparison with those of the Third World. At the worst, however, East European debts will be far smaller than those of the non-OPEC countries of the Third World, even if they rise from \$26 billion, more or less, the level estimated for end 1976, to roughly twice that amount by 1980. Moreover, the East European countries have far better long-run prospects for doing without massive assistance. They are all industrialized countries, even though Romania has obtained useful recognition as a “developing country.” Under continued pressure they should be able to reduce their hard currency balance-of-payments deficits to a manageable level.

The logical Western objective in economic relations with East European countries would be to get them to follow such a course. That would involve a right-about-face in the attitudes of Western governments, which have allowed when they have not encouraged and supported the expansion of credit to Eastern Europe. It would require wide cooperation not only to provide necessary very long-term financing but also to control future expansion of credit, not only with government backing but also by commercial banks at their own risk. The package ought to include commercial concessions and technical aid that would help to assure continued growth of trade.

The chances of getting such an agreement at the moment do not appear strong. Substantial economic recovery would improve the chances. An immediate risk of East European default would further improve them. Even so, the obstacles are great. Apart from commercial rivalries and the interests of protected industries, it would be necessary to overcome resistance from commercial bankers, still “awash with

lendable funds," as one of them put it. Finally, Western leaders have more pressing issues to resolve.

Most existing international organizations—the IMF and IBRD, the UN's Economic Commission for Europe, the European Communities, NATO—are evidently unsuitable, if only because membership is too limited or too broad. OECD appears to offer the best forum for exploring the problem. Continued examination of the issues by OECD would seem to be a useful, perhaps indispensable basis for timely action.

If concerted Western action is not taken during the next upswing in the world economy, a serious breakdown in East-West trade is possible. Without some such action, East European debts will approach an unmanageable level by the early 1980s at the latest. Although outright default might be avoided, commercial banks would find it increasingly hard to justify a further expansion of credit to Eastern Europe. The steady growth of trade with the developed West would end—trade might indeed decline—and the East European countries would shortly have to cut back economic growth.

The political consequences might well take some time to develop, and would depend in part on just how severe and durable the economic consequences proved to be. Over some time, however, one can scarcely doubt that the East Europeans would see as ended two decades of "peaceful economic competition with the capitalist world." The outlook would be less hopeful for them and for Europe generally.

#### APPENDIX A. CALCULATION OF SOVIET-EAST EUROPEAN TRADE IN MATERIALS

The figures in Table 1 reflect Soviet data, which include re-exports, whether or not they reach the USSR. As a matter of convention they are converted to dollars, at the pre-Smithsonian rate of .9 ruble=\$1. This rate is used for the 1974 data as well, to facilitate comparisons over time. The data represent total exports and imports to the several countries, less machinery and equipment (CTN 1) consumer goods (CTN 9), and military end items (in unitemized residual).

The figures for machinery and equipment are the totals in Soviet data (converted). The definition was changed slightly in 1972; the new definition is reflected in the 1970 and 1974 data.

The figures for consumer goods are totals of entries given; they are slightly low, therefore.

The figures for Soviet arms deliveries (to be taken in the broadest sense) are based on Barry L. Kostinsky, "Description and Analysis of Soviet Foreign Trade Statistics," Foreign Economic Report (FER) No. 5, July 1974, pp. 56-73 and 113-16; and various editions of ACDA, "World Military Expenditures and Arms Trade," in particular those covering 1963-73 and 1965-74. East European imports in 1965 and 1970 are ACDA estimates of imports from all sources, less 5% to account approximately for deliveries from Czechoslovakia and Poland, as shown (only in cumulative form) by ACDA. For 1960 they reflect the ACDA estimates for 1961 (reduced by 5%) and the changes from 1960 to 1961 in unitemized Soviet exports to East European countries, the basis for such estimates through 1967. They represent the middle of a probable range. For 1974 the estimates are ACDA estimates, again reduced by 5 percent. The ADCA estimates in "current dollars" for 1974 are reconverted at the pre-Smithsonian exchange rate on the assumption that they reflect basic ruble estimates; that is they are deflated by the difference between the 1970 and 1974 ruble/dollar rate.

The figures for Soviet arms imports for 1960 and 1965 are derived from Kostinsky's demonstration that the residuals in Soviet imports from Czechoslovakia and Poland through 1967 are almost entirely military end items; the figures represent the upper end of a range. For 1970, he makes a direct estimate for Czechoslovakia (p. 114), which is used. For 1974, the estimates are based on ACDA cumulative series and estimates for 1964. A figure for Poland in 1970 is interpolated.

According to ACDA estimates, GDR military exports are very small. The residual in Soviet imports from the GDR through 1967 unquestionably reflects very largely uranium deliveries, but estimates of GDR arms deliveries as high as \$16 million in 1960 and \$32 million in 1965 are consistent with available evidence. (Deliveries of goods to Soviet forces in East Germany are not in question; throughout Eastern Europe all such deliveries are paid for through noncommercial accounts.) Since there is no known way of estimating GDR arms shipments for later years, none is entered for any year. The figures for GDR exports under CTN 2-8 (which represent a residual in total exports) are thus a little high.

The derivation of most estimates of Soviet deliveries of military end items after 1967 is uncertain. But at least the total of ACDA figures for such deliveries to all Communist countries in 1974 is consistent with aggregate Soviet export data. That is, the total is a little less than the residual in Soviet exports to these countries left after subtracting the major elements shown (as percentages) in *Vneshnyaya torgovlya* under "Struktura eksporta SSSR/v sotsialisticheskie strany" (covering CTN 1, 21-24, 26-27, 3, 50-52, 7-9) together with totals of country data given (and partner data available) for the missing items (250, 4, 53, 55-59, and 6)

The figures for CTN 2-8 include any element in the residual not included in arms deliveries (such as GDR uranium deliveries to the USSR). In the case of the GDR, exports to the USSR under CTN 2-8 are somewhat overstated, as noted above, because no estimate is included for GDR shipments of military end items. CTN categories 2-8 include principally fuels, ores, nonmetallic minerals, metals, and certain metal products (CTN 2); chemicals and rubber (CTN 3); building materials (CTN 4); wood and wood products, natural textiles fibers, hides and skins, and technical fats (CTN 5); live animals (CTN 6); food raw materials (CTN 7) and processed foods and beverages (CTN 8).

## APPENDIX B. COMMODITY COMPOSITION OF EAST EUROPEAN TRADE BY AREA

Judgments on the shares of the Communist world and the West in East European imports by commodity group reflect East European statistics, broken down by CTN categories. Many of the sources have been cited, and used, by J. M. Montias and his former student Jozef M. van Brabant. See in particular, Prof. Montias' article, "The Structure of Comecon Trade and the Prospects for East-West Exchanges," *Reorientation and Commercial Relations of the Economies of Eastern Europe*, printed for the Joint Economic Committee, 16 August 1974, pp. 662-81; and Dr. van Brabant's, "A Reconstruction of the Composition of Intra-CEMA Trade Relations" (No. 107, *Berichte des Osteuropa-Instituts an der Freien Universität Berlin*, West Berlin, 1975).

Useful articles for updating their work include the following:

Peter Farkas *et al.*, "Magyarország és a fejlődő országok közötti gazdasági kapcsolatok néhány középtávu tendenciájának előrejelzése," *Közgazdasági szemle*, No. 6, 1973, pp. 649-66.

Vera Ivanova, "Bulgarian Trade Relations with the Developed Capitalist Countries," *Ikonomicheska misul*, No. 1, 1974, pp. 32-41 (JPRS 62619, 31 July 1974).

V. Moiseenko, "Spetsializatsiya i kooperirovanie proizvodstva vazhnyy faktor vzaimnoy torgovli stran-chlenov SEV," *Ekonomicheskoye sotrudnichestvo stran-chlenov SEV*, No. 6, 1975, pp. 85-8.

Zdeněk Orlíček, "30 Let československého zahraničního obchodu," *Zahraníční obchod*, No. 5, 1975, pp. 1-5.

Mikhail Savov, "Razvitie na vzaimniya stokoobmen i sutrudnichestvoto v oblastta na vunshnata turgoviya mezhdou stranite—chlenki na SIV," *Vunshna turgoviya*, No. 11, 1975, p. 7-12.

Materials in statistical yearbooks and economic periodicals, together with some unpublished data, provide complete (or nearly complete) breakdowns for 1960, 1965, 1967, 1970, 1974, and 1975 for Hungary and Romania. For Czechoslovakia, SITC data were converted to a CTN basis to supplement the published breakdowns. Polish 3- to 6-digit CTN data were compiled for 1960-68 and a rough conversion made of later data in the Polish industrial code, in order to get more or less satisfactory breakdowns. Partner country data were used to piece out estimates for the trade of Bulgaria and the GDR in 1965 and the 1970's.

The resulting series would have to be adjusted for differences in price levels and trends to give an accurate idea of the structure and development of trade with various areas. This phase of the work is yet to be done systematically. Rough adjustments have been made, however, using data presented by Marer, *op. cit.*, for the 1960's and published and estimated price indexes for the 1970's. See appendix C. The adjustments are believed to be good enough to support the general conclusions given in the text.

For data on specific types of machinery and equipment imported from East and West, the main reliance has been put on unadjusted, often incomplete data published by the East European countries in various commodity codes. For chemical equipment, see Harold K. Lent, Jr., "East European Chemical Production and Trade," Reorientation and Commercial Relations of the Economies of Eastern Europe, printed for the Joint Economic Committee, 16 August 1974, pp. 406-20. Otherwise, see the various countries' statistical yearbooks (general and/or foreign trade); all but the GDR give a good idea of the breakdown, though it would be hard to compile comparable estimates. Partner country statistics plus the CEMA statistical yearbooks give a general impression for the GDR.

### APPENDIX C. PRICE CHANGES AND REAL GROWTH OF IMPORTS AND EXPORTS, 1960-75

The real growth of imports from the West and from the Communist world in 1961-75 (Table 2) and of exports to the West in 1971-75 (p. 42) is estimated from official data of the East European countries themselves, extended when necessary by the use of Hungarian price indexes.

In the one case, that of the GDR, official statistics directly provide data on imports and exports at "comparable" prices, *in toto* and with the Communist world in 1960-69;<sup>2</sup> and on total imports, total exports, and turnover with major areas in 1971-75. The real growth of imports from and exports to the Communist countries and the West from 1970 to 1975 is calculated with the help of an estimate of the real growth of exports to Communist countries. See Table C-1. The implied price indexes are given in Table C-2.

TABLE C-1.—ESTIMATED INCREASES FROM 1970 TO 1975 IN GDR EXPORTS TO AND IMPORTS FROM COMMUNIST COUNTRIES AND THE WEST

	1970 (million VM) <sup>1</sup>	Index (1970 equals 100)	1975 (million VM)
<b>Exports:</b>			
Communist countries.....	14, 221. 2	§ 157. 4	22, 384
West.....	5, 019. 1	(147. 8)	§ 7, 419
Total.....	§ 19, 240. 2	§ 154. 9	29, 803
<b>Imports:</b>			
Communist countries.....	14, 118. 9	(142. 5)	§ 20, 117
West.....	6, 238. 3	(139. 6)	§ 8, 709
Total.....	§ 20, 357. 2	§ 141. 6	28, 826
<b>Turnover:</b>			
Communist countries.....	28, 340. 1	§ 150. 0	42, 501
West.....	11, 257. 4	§ 143. 3	16, 128
Total.....	§ 39, 597. 4	§ 148. 1	58, 629

<sup>1</sup> "Statistisches Jahrbuch der DDR 1975," pp. 262-3, also in earlier editions.

<sup>2</sup> The annual increase in exports to socialist countries (at "comparable prices" is given at 10 percent per year in the draft directives for 1976-80, "Neues Deutschland," Jan. 15, 1976, p. 4. This rate has been scaled down to 9.5 percent in view of the overall effect on implied price indexes.

<sup>3</sup> Residuals.

<sup>4</sup> Totals differ from sums of items as a result of rounding.

<sup>5</sup> As given in "Statistisches Jahrbuch der DDR 1976," p. 264. Resulting totals for turnover have been adjusted downward for rounding so as to add to totals of exports and imports.

<sup>6</sup> The calculation of trade with the West and the implied price indexes are given by Paul Marer, "Postwar Pricing and Price Patterns in Socialist Foreign Trade." (IDRC Report 1), Indiana University, 1972, p. 77.

TABLE C-2.—IMPLIED-PRICE INDEXES IN GDR TRADE IN 1975  
(1970=100)

	At 1970 prices (million VM) <sup>1</sup>	At 1975 prices (million VM) <sup>2</sup>	Implied price index (1970=100) <sup>3</sup>
Exports:			
Communist countries .....	22,384	25,668	114.7
West .....	7,419	9,418	126.9
Imports:			
Communist countries .....	20,117	26,145	130.0
West .....	8,709	13,119	150.6

<sup>1</sup> From table C-1, above.

<sup>2</sup> From "Statisticheskiy yezhegodnik stran-chlenov SEV 1976," p. 341, converted at the rate 4.667 VM=1 ruble.

<sup>3</sup> These derived indexes are all lower than Hungarian indexes, especially for imports. Differences in this direction would be expected for exports as a result of differences in composition—the higher share of machinery and lower share of foodstuffs and raw materials in GDR exports, both to Communist countries and to the West. For imports from Communist countries, a small difference in the same direction is suggested by data for Soviet trade in Martin Kohn, "Developments in Soviet-Eastern European Terms of Trade, 1971-1975," "Soviet Economy in a New Perspective," printed for the Joint Economic Committee, Washington, Oct. 14, 1976, especially pp. 73-77. For imports from the West, one significant factor would suggest a lower price index, the smaller share of crude oil imports, as indicated by the absolute amounts shown in Haberstroh, pp. 379-395.

Otherwise, the basic data are those showing price changes, Fisher ideal indexes in the case of Hungary and Poland, unspecified in the other countries. For Hungary, for Poland after 1965, and for Czechoslovakia (in part) in the 1970's, data are available for overall price changes both with the Communist world and with the West.<sup>43</sup> For Romania, unpublished data indicate the extent of price changes (negligible) with both areas through 1968; for later years, nothing is available.<sup>44</sup> For Bulgaria, for Czechoslovakia in the 1960's, and for Poland in 1961-65, only price changes for a four-way CTN breakdown of total imports and exports are available. In these cases, therefore, Hungarian indexes are applied to trade data broken down in CTN groups to calculate price changes in trade with the Communist world, discussed in Appendix B. Estimates of imports from the West in constant prices are obtained as a residual. The implied price changes in imports from the West are quite consistent with what is given for Hungary.

The range of error in estimating the underlying official data on price changes is believed to be very small through 1970 in view of the relatively small changes and the fairly consistent pattern of changes in CEMA pricing. Even in the 1970's errors beyond a percentage point or two are quite unlikely except perhaps for 1975.

Hewett's work on intra-CEMA trade, moreover, indicates that independently calculated indexes of unit values will generally yield overall results not greatly different from the official indexes. It would nevertheless be particularly useful to carry out similar calculations for East European trade with the West, using Western data.

#### APPENDIX D. CALCULATION OF PERSONAL CONSUMPTION IN ROMANIA

Personal consumption in Romania is estimated from personal incomes, less direct taxes and savings. Gross personal incomes in 1970 are calculated from absolute increases in "real personal incomes" (110 billion lei in 1966-75 and 74 billion lei in 1971-75) and the corresponding percentage increases (91% and

<sup>43</sup> The important sources include:

For Czechoslovakia:

S. Potáček, "Devizové hospodářství do popředí pozornosti," *Hospodářské noviny*, 4 May 1975, pp. 1, 5.

Peter T. Leach, "Czech Five Year Plan Growth Target Lowered," *Journal of Commerce*, 23 September 1975, p. 10. This article quotes Minister of Foreign Trade Andrej Barcak.

*Svet hospodářství*, 8 January 1976, p. 1 (interview with Minister Barcak).

For Hungary:

*Külkereskedelmi statisztikai évkönyve*, 1975, pp. 407-30.

Adam Marton, "A magyar külkereskedelmi árak változásai és a tőkés világgpiaci áralakulás," *Külgazdaság*, No. 8, 1976, pp. 563-78. Marton is the best known Hungarian expert on foreign trade prices.

For Poland:

K. Chinowski, Anna Stepniewska, "Terms of Trade polskiego handlu zagranicznego," *Rynki z zagranicze*, 16 December 1971, p. 3. Anna Stepniewska, Hanna Molewicz, "Terms of trade polskiego handlu zagranicznego," *Handel zagraniczny*, July 1976, pp. 35-38.

<sup>44</sup> In an interview on 21 July 1975 with a correspondent from *Le Monde*, Ceausescu did indicate that price increases in recent years for imports from the West had been "somewhat offset" by price increases for exports. *Romania/ Documents—Events*, No. 31, 1975, p. 57.

46%. See Nicolae Bozdog, "Amplificarea dimensiunilor și funcțiilor economico-sociale ale comerțului socialist," and Ioan Ravar, S. Muntean, "Ridicarea nivelului de trai și civilizație al oamenilor muncii țelul suprem al politicii partidului," both in *Revista economica*, No. 33, August 20, 1976, pp. 16, 14, respectively, and "Anuarul statistic al RSR 1975" p. 52. The resulting 1970 figure of 152 billion lei yields a per capita figure of about 7,550 lei, believed to have been deflated to a 1963 base. The official index for the cost of living in 1964-70 rose about 2 percent, bringing the per capita figure in 1970 lei to about 7,700 lei. Direct taxes were about 575 lei per capita (total is from "Anuarul statistic al RSR 1975," p. 408) and savings about 225 lei per capita,<sup>45</sup> leaving a figure of 6,900 lei per capita for income spent for goods and services. A factor of 13 percent is added for consumption in kind, by analogy with Bulgaria and Yugoslavia in 1968 (see Maria Elisabeth Ruban, *et al.*, *Die Entwicklung des Lebensstandards in den osteuropäischen Ländern* (DIW Sonderheft 108), West Berlin, 1975, pp. 94, 100), producing a total personal consumption of about 7,800 lei per capita. (Of the cash expenditures, about 4,800 lei was spent in socialist retail trade, 800 lei in the free market, 550 lei for housing, insurance, and the like, and 750 lei for other services. Cf. breakdown in Georges Caranfil, "Le pouvoir d'achat du 'leu' roumain," *Revue de l'est*, No. 2, 1970, esp. pp. 140-53.)

## APPENDIX E. ESTIMATES OF THE PROJECTED TRADE OF EASTERN EUROPE IN 1976-80

The East European countries published less for 1976-80 on projected increases in trade than for earlier periods. A good deal has still appeared on trade with the Communist world, but very little on trade with the West.

Information on projected turnover with other CEMA countries is available, sometimes in toto and otherwise by country, and for projected trade with Yugoslavia. Little or nothing has appeared on projected turnover with the Far East Communist countries, partly because there have been few 5-year trade agreements. Public statements sometimes note the price basis used for the absolute data, or increases, announced; in most other cases, the probable basis can be inferred.

All countries but Bulgaria and Romania have also put out information on increases in trade with the Communist countries from 1975 to 1980—either on exports (the GDR) or on exports and imports (Czechoslovakia, Hungary, and Poland). These figures, too, must be reviewed in the light of whether they reflect constant ("comparable") 1974 or 1975 prices, or instead reflect projected current prices, as they sometimes do. Increases reflecting 1974 constant prices, which must sometimes be used, must be adjusted downward—with 1974 price weights, higher rates of increase are obtained than with 1975 weights, chiefly as a result of major increases in 1975 CEMA prices of slow growing raw materials trade and relatively smaller increases for the rapidly-growing trade in machinery.

With these precautions, the projected increases in exports to and imports from the Communist world can be approximated except for Bulgaria and Romania. For Bulgaria it is possible to calculate the projected balance with the U.S.S.R., and that with Hungary is given. For Romania one is reduced to estimating directly the cumulative trade balance over the period.

Projected increases in trade with the West are given by Czechoslovakia and Hungary. For Poland, the projected increases, as revised in late 1976, may be inferred from the increases projected in exports and imports overall and with the Communist world. For the GDR, rough estimates can be calculated from estimates of trade with the Communist world, a believable statement that there would be little change in the share of the Communist world in total trade, and an estimate that the projected increase in overall exports was at least as great as the increase (at "comparable prices") achieved in 1971-75, with allowance for the effect of a shift to 1975 price weights.

Estimates for Romania involve an analysis of three stages of the Romanian foreign trade plans. In the first two drafts, total exports and imports were projected from the expected results in 1971-75, the first in 1973 prices, the second in 1974 prices. It is assumed that the final plan projected the same volume of ex-

<sup>45</sup> Estimated on the basis of the lowest real income in the area and an intermediate rate of growth of nominal income. An even lower figure, only about one-half the estimate, would be obtained by linking (with interpolation) Montias' series for savings deposits through 1964 (J. M. Montias, "Economic Development in Communist Rumania," Cambridge, Mass., 1967, p. 74) with the index numbers (1965 base) for 1965 and 1970 cited by Maria Elisabeth Ruban, *et al.*, in the work cited just below in the text, p. 155.

ports and imports as the first two plans; the resulting estimate is adjusted to take account of shifts in price weights from 1974 and 1975. Projected trade with the West is then obtained as a residual after subtracting estimated trade with the Communist world.

TABLE E-1.—PROJECTION OF BULGARIA'S TRADE WITH COMMUNIST COUNTRIES, 1976-80

	1975 (million rubles) <sup>1</sup>	1980	
		Index (1975=100)	Million rubles
Exports.....	2,794	(151.0)	* 4,219
Imports.....	2,910	(133.0)	* 3,870
Turnover.....	5,704	(141.8)	* 8,089

<sup>1</sup> "Statisticheskiy yezhegodnik stran-chlenov SEV, 1976," p. 341.

<sup>2</sup> Projected exports to and imports from Communist countries are calculated from projected turnover and cumulative trade balances with the U.S.S.R. and Hungary. For lack of any other information, an aggregate net balance is assumed in projected trade with other countries. The surplus with the U.S.S.R. is estimated from the statement that Bulgarian machinery and equipment deliveries to the U.S.S.R. would double in the period and would constitute 50 percent of total exports. (Y. Tenov, "Sotsialisticheskiy internatsionalizm v deistvii," "Ekonomicheskaya gazeta," No. 37 September 1976, p. 20). Elsewhere (A. Ketkovich, "Vsaimovigodnoye sotrudnichestvo," "Sovetskaya torgovlya," Apr. 1, 1976, p. 3) it is specified that the proportion would be 49 percent over the period. Thus (on a flat rate basis) machinery exports to the U.S.S.R. would be about 6,030,000,000 rubles in the period, and Bulgarian total exports would be 12,300,000,000 rubles. Given a total turnover of 24,000,000,000 rubles (as given; e.g., by M. Loshakov, A. Polyenko, "Soviet Trade with the European Socialist Countries: Results and Prospects," "Foreign Trade U.S.S.R.," No. 12, 1976, p. 9), imports would be 11,700,000,000 rubles, and the surplus 600,000,000 rubles. This is reasonable in view of the 670,000,000 rubles in participation in Soviet project scheduled for 1976-80 (e.g., FBIS, "Daily Report," Eastern Europe, Jan. 5, 1976, p. C1, citing BIA broadcast in English, Dec. 27, 1975). To the 600,000,000 ruble surplus with the U.S.S.R. is added a 70,000,000 ruble (403,000,000 rubles—332,000,000 rubles, in 1975 prices) surplus with Hungary. See "Vilaggazdasag," Dec. 6, 1975, 0. p. The resulting projections for 5-yr cumulative exports (18,000,000,000 rubles) and imports (17,330,000,000 rubles) are then used (on a flat rate basis) to project increases in exports and imports to 1980.

<sup>3</sup> Turnover represents the sums of trade agreements for 1976-80 plus estimates for other countries. For Soviet trade at 24,000,000,000 rubles, see Loschakov and Polyenko, op. cit. For trade with the GDR, given as 16,000,000,000 VM, see Stefan Sharenkov, "Sotrudnichestvo mezhdu NRB i stranite-chlenki na SIV," "Politicheskaya agitatsiya," No. 14, 1976, pp. 61-67 (JPRS 68143, Nov. 1, 1976). For trade with Poland, at 2,200,000,000 rubles, see BBC, "Summary of World Broadcasts," pt. 2, Eastern Europe, SWB EE/W869/A/2, Jan. 29, 1976, citing BTA broadcast in English, Jan. 16, 1976. For trade with Czechoslovakia, the figure of 1,800,000,000 rubles is an estimate based on Sharenkov, op. cit. For Hungary, the figures cited above totaling 735,000,000 rubles, are taken from "Vilaggazdasag," loc. cit. The figure for trade with Romania, 1,000,000,000 rubles, is from RFE, "Romanian Situation Report/21" June 6, 1975, p. 6. The figure for Cuba, 700,000,000 rubles, is based on a statement that trade in 1976-80 would be 65 percent greater than in 1971-75. Sofia BTA in English, Dec. 25, 1976, citing "Rabotnicheskoy delo" of the same day, as given by JPRS 68506, Jan. 19, 1977, p. 4J. The figure for Yugoslavia, 1,000,000,000 rubles, comes from "Privredni pregled," Dec. 15, 1976, p. 2. The figures for Mongolia, 100,000,000 rubles, and other Communist countries, 400,000,000 rubles, are rough estimates assuming somewhat the same expansion of trade as before.

TABLE E-2.—PROJECTION OF CZECHOSLOVAKIA'S TRADE,<sup>1</sup> 1976-80

	1975 (million crowns)	1980	
		Index (1975=100)	Million crowns
Exports:			
Communist countries.....	33,377	141.5	47,228
West.....	13,274	153.9	20,429
Total.....	46,651	(145.0)	67,657
Imports:			
Communist countries.....	35,399	127.2	45,028
West.....	15,317	114.9	17,599
Total.....	50,716	(123.5)	62,627
Turnover:			
Communist countries.....	68,776	(134.1)	92,256
West.....	28,591	(133.0)	38,028
Total.....	97,367	(133.8)	130,284

<sup>1</sup> Projections for exports and imports adjusted from plan data at 1974 prices. The overall increases were 42.7 percent for exports and 24.4 percent for imports (32.5 percent for turnover). For trade with the Communist world exports were to rise 46.3 percent imports 32 percent, and turnover 39.2 percent. From article in Bratislava "Pravda," by Deputy Prime Minister Rudolf Rohlicek, Jan. 19, 1976, quoted in British Embassy "Press Review," No. 12, Jan. 20, 1976, p. 4. The projections for trade with the West, obtained as a residual from the original data, are left with little change; price changes on the world market from 1974 to 1975 would have little effect on them.

TABLE E-3.—PROJECTION OF GDR TRADE, 1976-80

	1975	1980	
	(billion valuta mark) <sup>1</sup>	1975=100	Billion valuta mark
<b>Exports:</b>			
Communist countries .....	25.68	146.0	37.49
West .....	9.42	(160.9) (164.6)	15.16 15.51
<b>Total</b> .....	<b>35.10</b>	<b>150.0</b> <b>151.0</b>	<b>52.65</b> <b>53.00</b>
<b>Imports:</b>			
Communist countries .....	26.16	(126.2)	33.01
West .....	13.13	(118.1) (115.5)	15.51 15.16
<b>Total</b> .....	<b>39.29</b>	<b>123.5</b> <b>122.6</b>	<b>48.52</b> <b>48.17</b>
<b>Turnover:</b>			
Communist countries .....	51.84	136.0	70.50
West .....	22.55	136.0	30.67
<b>Total</b> .....	<b>74.39</b>	<b>136.0</b>	<b>101.17</b>

<sup>1</sup> Data from Statisticheskiy yezhegodnik stran-chlenov SEV, 1976, p. 341, converted to VM and compared with data on turnover in Statistisches Jahrbuch der DDR 1976.

<sup>2</sup> The 5-yr plan increase is projected at 50 percent for exports, (see Neues Deutschland, Dec. 17, 1976, p. 3), but is adjusted downward to 46 percent for the effect of shifting from 1974 prices, in which the planning was done (see Neues Deutschland, Jan. 15, 1976, p. 4) to 1975 prices.

<sup>3</sup> Residuals.

<sup>4</sup> It is presumed that the GDR intends to do at least as well on exports (in real terms) as in 1971-75, when they rose (at 1970 prices) by 54.9 percent. Statistisches Jahrbuch der DDR, 1976, p. 264. At 1975 prices, that would be equivalent to a 50-51 percent increase, mainly because of the reduced weight of machinery and equipment, the most rapidly growing sector, and the increased weight of fuels and foodstuffs, the most slowly growing.

<sup>5</sup> Turnover with the Communist world in 1980 is derived as follows. Projected 1976-80 turnover of 54,000,000,000 rubles, 1974 prices with CEMA (Neues Deutschland, Nov. 27, 1975, p. 4), is multiplied by 1.1787 to convert to 1975 prices, making 63,650,000,000 rubles. A total of \$2,800,000,000 projected for trade with Yugoslavia, presumed to be in 1975 prices (Belgrade domestic service, Jan. 10, 1977, reported in FBIS Daily Report, Eastern Europe, Jan. 11, 1977, p. 18), is converted to 2,130,000,000 rubles. The total of 65,780,000,000 rubles is 6,040 times the 1975 figure based on 10,890,000,000 rubles with CEMA plus Yugoslavia, yielding an increase (flat rate projection) of 36 percent in 1980 over 1975.

<sup>6</sup> Total trade with the West is projected as remaining the same share as in 1975, on the strength of what foreign trade officials told the Reuters reporter in Leipzig. East-West Trade News, Sept. 15, 1976, p. 3. The same reporter also noted, on this and other occasions, that the GDR hoped to double trade with the West.

<b>Total</b> .....	<b>8,645</b>	<b>(143.3)</b> <b>(148.3)</b>	<b>12,386</b> <b>12,823</b>

<sup>1</sup> As given in "Statisticheskiy yezhegodnik stran-chlenov SEV," pp. 339, 341.

<sup>2</sup> BBC, "Summary of World Broadcasts," pt. 2, Eastern Europe, Weekly Economic Report, SWB EE/W856/A/10, Dec. 4, 1975, quoting a broadcast on Nov. 20, 1975, by Gyula Kovacs, Deputy Minister of Foreign Trade. The upper limit shown for exports to the West is extrapolated to produce a spread of 5 percentage points in overall turnover; Kovacs spoke of an increase of 45 percent to 50 percent. Later figures are similar, though not identical.

<sup>1</sup> "Rocznik statystyczny handlu zagranicznego 1976," p. 4.

<sup>2</sup> Residuals.

<sup>3</sup> The projections for trade with the West are based on the following statement: "The growth rate of export to capitalist countries will almost double as compared with the last 5-year period, the level of import being stable." Press release on Sejm committees' work, Warsaw PAP in English, Dec. 4, 1976, reported FBIS, "Daily Report," Eastern Europe, Dec. 6, 1976, (p. G10). The calculated rate of growth of exports to the West in 1971-75 (real growth) is 7.4 percent, based on Polish data on price changes (see app. C), and that rate is doubled.

<sup>4</sup> The original announcement of the revised plan goals for foreign trade was in Gierek's speech to the 5th Plenum of the PZPR, Dec. 1, 1976, reported from Warsaw domestic service, same day, in FBIS, "Daily Report," Eastern Europe, Dec. 3, 1976, p. G14. The goal for exports was there given as an increase of "over 75 percent; that for imports as an increase of 26 percent. The more precise figure used here for the increase in imports was given in "Polityka," Dec. 18 1976, p. 6.

<sup>1</sup> "Anuarul statistic al RSR 1976," pp. 376ff.

<sup>2</sup> Projected exports to and imports from Communist countries are derived from projected turnover for the period, on the assumption of a 700,000,000 ruble cumulative surplus with CEMA and some surplus with the PRC, and the resulting exports and imports in 1976-80 are used to project the increases from 1975 to 1980 at a flat rate.

<sup>3</sup> Projected exports to and imports from the West are residuals after subtracting projected exports to and imports from Communist countries from total exports and imports.

<sup>4</sup> Projected exports to Western developed countries are a residual after subtracting projected imports from the projected turnover.

<sup>5</sup> Projected exports to and imports from developing countries are residuals after subtracting exports to and imports from developed countries from the totals for trade with the West.

See balance of footnotes on page 52.

There is very little to go on in estimating Bulgaria's projected trade with the West. The 5-year plan law does provide that "foreign trade volume must increase" by 60 percent from 1975 to 1980. See *Rabotnichesko delo*, 30 August 1976, p. 1. But this figure almost certainly includes some allowance for trade with Communist countries over and above the 44 percent increase indicated by the trade agreements. Accordingly a residual estimate of trade with the West cannot be made.

## APPENDIX F. PROJECTED TRADE BALANCE BETWEEN THE USSR AND CEMA AND EAST EUROPEAN PARTICIPATION IN SOVIET PROJECTS, 1976-80

The projected trade balance of the U.S.S.R. with the CEMA countries as a group, closely related to the East European aggregate trade balance with CEMA, can be estimated with some precision, but only in projected current prices. The basis is a set of figures on total projected Soviet exports and imports of machinery of almost 57 billion rubles in trade with CEMA in 1976-80, in absolute terms and as percentages of total trade. The result, out of a trade turnover of just under 150 billion rubles, is a Soviet import surplus of 4.4 billion rubles. (See table F-1).

TABLE F-1.—PROJECTED SOVIET TRADE WITH CEMA, 1976-80

	Soviet exports	Soviet imports
Machinery and equipment 1971-75 (million rubles) <sup>1</sup> .....	11, 138	19, 189
Index for 1976-80 (1971-75=100) <sup>2</sup> .....	1. 79	1. 92

Share of machinery and equipment in total trade (ratio) <sup>2</sup> .....	275	479
Total projected trade (billion rubles).....	72, 498	76, 919

<sup>1</sup> Standard Soviet trade statistics, CTN 1.

<sup>2</sup> "DDR Aussenwirtschaft," Jan. 19, 1977, p. 2.

At 1975 prices, the projected trade was smaller, about 133 billion rubles, and the trade in machinery only 52 billion rubles. (See table F-2.)

<sup>4</sup> Increases in total exports and imports are projected from earlier stages of Romanian plans for 1976-80, after allowing for changes in the price basis. The first stage was announced in draft directives to the 11th RCP Congress in August 1974 ("Scinteia," Aug. 3, 1974, pp. 1-6A.) This document projected trade in 1971-74 and 1971-75 in constant prices and stated that in 1976-80 trade would rise 72-80 percent, exports by 75-85 percent, and imports 60-70 percent over the projected 1971-75 total. Presumably 1973 prices were used. A 2d stage dating from early 1976 calls for a rise of 80 percent in trade over 1971-75, with exports to rise 90 percent and imports by about 60 percent. See, for example, Mihai Părăuțu, "Cininalul 1976-80, cincinalul revoluției tehnico-științifice. . . ." "Revista economica," No. 5, 1976, p. 18. The third stage is the 5-year plan law, which called only for an increase of from 90 percent to 101.4 percent in 1976-80 over 1971-75, but in this case almost certainly the comparison is with a current price base. "Scinteia," July 3, 1976, pp. 2-3. The increases shown in the text reflect estimates of 210,000,000,000 lei for projected exports and 179,000,000,000 lei for projected imports in 1976-80, based on a rough adjustment of the 2d stage plan. The turnover figure of 389,000,000,000 lei falls near the top of the 372-394,000,000,000 lei that would be obtained from the final plan. So exports, or imports, or both, may be overestimated a little. In any case, the projections reflect not only price changes but also the fact that in real terms exports fell short of plan in 1975 as in 1974 by considerably more than imports.

<sup>7</sup> Projected imports from developed countries assume no increase over 1975.

<sup>8</sup> Turnover with Communist countries is projected on the basis of trade agreements with all partners except Cuba and the Far East Communist countries, for which rough estimates are made. The Soviet figure, from various sources, is given as 9,000,000,000 rubles, which by association may be determined to be in 1975 prices, as in M. Loshako, A. Poliyenko, "Soviet Trade with the European Socialist Countries: Results and Prospects," "Foreign Trade U.S.S.R.," No. 12, 1976, p. 9. The figure with Poland is 2,300,000,000 rubles, from BBC, "Summary of World Broadcasts," pt. 2, Eastern Europe, Weekly Economic Report, SWB EE/W847/A/7, Oct. 2, 1975, quoting a broadcast of PAP in English of Sept. 23, 1975. This figure may be in 1974 prices, and hence low; there is a later figure of 2,800,000,000 rubles (FBIS, "Daily Report," Eastern Europe, Jan. 31, 1977, p. H4, from an Agerpres broadcast of Jan. 30). The figure for Czechoslovakia is 2,400,000,000 rubles, from the increase over 1971-75 indicated by Ion Patan in an interview in "Zemedeiske noviny," Apr. 1, 1976, p. 2, as cited FBIS, "Daily Report," Eastern Europe, Apr. 15, 1976, p. H16. For Hungary, a figure of 1,400,000,000 rubles is projected on the basis of a statement that the trade in 1980 would be double the 1975 level. "Journal of Commerce," Jan. 23, 1976, p. 6. A figure of 1,100,000,000 rubles is projected for Bulgaria from the statement that trade would double the 1971-75 level e.g., "DDR-Aussenwirtschaft," May 12, 1976, p. 3. The figure for the GDR is 5,000,000,000 rubles ("Journal of Commerce," Jan. 23, 1976, p. 6). The figure for trade with Yugoslavia is 2,400,000,000 rubles (BBC, "Summary of World Broadcasts," pt. 2, Eastern Europe, Weekly Economic Report, SWB EE/W860/A/19, Jan. 8, 1976, based on a Belgrade home service broadcast of Dec. 25, 1976).

<sup>9</sup> Turnover with the developed West is a residual, the total projected turnover with the West less projected turnover with developing countries.

<sup>10</sup> Turnover with developing countries is projected at 30 percent of the total, on the basis of often repeated Romanian statements. See, for example Ion Pătan, "Politica României de colaborare economică cu țările în curs de dezvoltare," "Revista economica, No. 23, 1976, p. 6.

To calculate the projected balance at those prices, it seems reasonable to suppose that the implied inflation of machinery and equipment prices (about 9 percent) was shared proportionally between Soviet imports and exports. The implied inflation for other goods—15 percent overall—presumably was somewhat greater for Soviet exports than for imports, chiefly because the former reflect the continued introduction of the world market price rises of 1973-75 for fuels. With a modest adjustment for this difference (16 percent for Soviet exports, 13 percent for Soviet imports), it would appear that the Soviet import surplus in 1975 prices would have been projected at about 6.1 billion rubles (or \$8.2 billion). (See table F-2.)<sup>46</sup>

TABLE F-2.—PROJECTED SOVIET TRADE WITH CEMA, ADJUSTED FOR PROJECTED PRICE CHANGES, 1976-80

	Soviet exports			Soviet imports		
	At current prices (billion rubles) <sup>1</sup>	Price deflator (1975=100)	At 1975 prices (billion rubles)	At current prices (billion rubles) <sup>1</sup>	Price deflator (1975=100)	At 1975 prices (billion rubles)
Machinery and equipment.....	19.94	<sup>2</sup> 109.0	18.20	36.84	<sup>2</sup> 109.0	33.80
Other goods.....	52.56	<sup>3</sup> 116.0	45.31	40.48	<sup>3</sup> 113.0	35.78
Total.....	72.50		63.51	77.32		69.58

<sup>1</sup> From table F-1.

<sup>2</sup> The deflator for machinery and equipment is inferred from the given total, 56,900,000,000 rubles at current prices (as in table F-1), and 52,000,000,000 rubles, presumed to be at 1975 prices. See V. Karpich, "Proizvodstvenoto sotrudnichestvo mezhdu stranite ot SIV—osnova za progresivnoto razvitiye na tehniya stokoobmen," "Vunshna turgoviya," No. 9, 1976, p. 11.

<sup>3</sup> The deflators for all other goods reflect the total residual at current prices from table F-1, 92,600,000,000 rubles, and that at 1975 prices, the difference between 52,000,000,000 rubles for machinery (as above) and a total turnover of 133,000,000,000 rubles, from Gerhard Brendel, "Entwicklung der Aussenhandelsbeziehungen zwischen den RgW Ländern," "Deutsche Aussenpolitik," No. 10, 1976, p. 1505. As noted in the accompanying discussion, the deflators for "all other goods" are differentiated on an estimate of the impact of more rapid increases projected for fuel prices.

Of this total—by the very derivation—1.7 billion rubles (\$6.1 billion—\$4.4 billion) reflects the net terms of trade effects of projected price changes. That amounts to 2½ percent of total East European and Cuban exports over the period (at 1975 prices).

One big part of the remainder reflects East European deliveries to joint projects in the USSR, less the payback beginning in 1979-80. The total participation by Eastern Europe was projected at about 3.4 billion rubles, probably at 1975 prices—at current prices the amount would have run to about 4 billion.<sup>47</sup> of this amount, several hundred million will be invested in hard currency and a certain amount in services, leaving less than 3 billion rubles, further reduced by a few hundred million rubles in payback and by Soviet participation in joint projects in other CEMA countries.

Much of the remaining 2 billion rubles (or more) probably is explained by net Soviet exports of military hardware, less net East European earnings from invisibles. In 1974, judging from ACDA estimates, the net Soviet surplus on military end items was about 860 million rubles<sup>48</sup> and one might conservatively project the total in 1976-80 at over 4 billion rubles. The East European offsets include interest payments, payback for previous "investment" in the USSR and net earnings from tourism. In addition, the East Europeans earn a substantial amount from the supply of goods and services to Soviet forces. The USSR presumably runs a net surplus on transport.

<sup>46</sup> An alternative indication is given by Karpich, who says "between 1975 and 1979" the participation of CEMA member countries in the construction of industrial projects on U.S.S.R. territory, in addition to obligations on long-term trade agreements, will reach about 8 percent of the volume of those exports to the U.S.S.R., "which would come to 5.6 million rubles."

<sup>47</sup> V. Karpich, "Proizvodstvenoto sotrudnichestvo mezhdu stranite ot SIV—osnova za progresivnoto razvitiye na tehniya stokoobmen," *Vunshna turgoviya*, No. 9, 1976, p. 10. For the higher figure, see, for example, interview with Soviet Deputy Minister of Foreign Trade, L. I. Zorin, "Foreign Trade U.S.S.R.," No. 8, 1976, p. 4.

# EAST EUROPEAN REACTIONS TO INTERNATIONAL COMMODITY INFLATION

BY ZBIGNIEW M. FALLENBUCHL, EGON NEUBERGER, AND LAURA  
D'ANDREA TYSON

## CONTENTS

I. Introduction.....	54
II. Case Study of Poland.....	55
III. The Case of Yugoslavia.....	85
IV. Comparisons and Conclusions.....	95

## I. INTRODUCTION

The international commodity inflation beginning in 1973 had serious economic consequences for the countries of Eastern Europe. Although each of these countries was affected by international economic disturbances, the impact and the reactions differed considerably among them. Some of the differences were clearly due to variations in the economic resource bases of these countries, while others were of a systemic nature. To illustrate these structural and systemic differences, we present case studies of two economies—Poland and Yugoslavia—which differ very greatly along both of these dimensions. The results presented here are preliminary and represent early results of work in progress on a major research project.<sup>1</sup>

The paper utilizes a particular conceptual framework—the impact model—to analyze the effects of worldwide inflation on the countries of Eastern Europe.<sup>2</sup> This model identifies four separate processes—generation, transmission, propagation and containment—by which world economic disturbances influence economic conditions in a particular country. The generation process focuses on the events and policies that give rise to an external economic disturbance—in this case the development of inflation in international markets. The transmission process examines the manner by which the external disturbance induces changes in the domestic producer prices and quantities of tradeable goods (exported and imported commodities). The propagation process encompasses the various channels by which these changes lead to further changes throughout the domestic economy. Finally,

<sup>1</sup> The work began under a grant from the Ford Foundation's International Competition on Research on the Soviet Union and Eastern Europe and is planned to culminate in a research conference in the summer of 1978 at the University of Windsor. Further results of the work on this project by the three authors of this paper, as well as by A. Brown, R. Portes, S. Rosefelde, and T. Wolf will be reported at the American Association for the Advancement of Slavic Studies Annual Convention in October. The 1978 conference will include theoretical papers by P. B. Kenen, L. Tyson, R. Portes, and T. Wolf, studies of Hungary (A. A. Brown), Poland (Z. M. Fallenbuchl), U.S.S.R. (S. Rosefelde), and Yugoslavia (E. Neuberger and L. Tyson), and an analysis of the political ramifications by A. Korbonski.

<sup>2</sup> A. A. Brown, Z. M. Fallenbuchl, J. A. Licari, and E. Neuberger, "The Impact of International Stagnation on Systemic and Policy Changes in Eastern Europe: Theoretical Reflections," in "The Soviet Union and Eastern Europe into the 80's: Multidisciplinary Perspectives," Simon McInnes (ed.), Oakville, Ontario: Mosaic Press, forthcoming.

the containment process includes all of the policies and changes in economic systems specifically designed to prevent the transmission and/or propagation of externally generated disturbances.

The effectiveness of the transmission and propagation processes—the facility and speed with which external events affect the internal economic situation—is a function of the nature of the existing economic system, of the development strategy that determines the structure of the country's imports and exports, of existing government policies, and of the efficacy of the containment mechanisms. A useful way to examine the containment process is to consider three major potential insulation layers, i.e., points at which the containment of imported economic disturbances can best be accomplished: (1) the foreign trade and exchange sector, where changes in world market prices can be prevented from causing changes in domestic wholesale prices of tradeables, and where attempts can be made to reduce somewhat the impact on the domestic economy of changes in foreign demands for the country's exports and supplies of the country's imports; (2) the consumer and producer trade networks, where changes in the wholesale prices and quantities of tradeables can be prevented from causing changes in the retail prices both of tradeables and nontradeables, and possibly also changes in the quantities of these goods available; (3) the labor market, where changes in the retail prices of consumer goods or their availability, which affect the standard of living, can be prevented from causing increases in wages, thereby breaking the price-wage-price spiral, or decreases in the availability of labor services.

The three authors collaborated in the planning of this study and in the writing of Section IV, Conclusions, but the two case studies were done independently, with Poland being done by Zbigniew Fallenbuchl, and Yugoslavia by Egon Neuberger and Laura Tyson; each of these authors are solely responsible for their own case study. We did not attempt to make the case studies parallel, but decided instead to stress in each study those features that were most interesting in the specific country. In addition, the significant differences in data availabilities and structural and systemic differences, as well as our desire to allow each author considerable flexibility, yielded two coordinated, yet highly differentiated studies.

## II. CASE STUDY OF POLAND

### 1. *Timing and Strength of the Impact of World Inflation on the Polish Economy*

In Poland import prices declined in 1971 and 1972 and then they increased by 8.8 per cent in 1973, 16.9 per cent in 1974 and 14.0 per cent in 1975. However, there were also considerable increases in export prices every year during that period and only in 1973 and 1974 was there a decline in the terms of trade (see table I).

TABLE I.—POLAND'S IMPORT AND EXPORT PRICES, TERMS OF TRADE AND THE STRUCTURE OF TRADE ACCORDING TO MAIN REGIONS, 1971-75

	Export and import prices and terms of trade (annual changes)					Structure of trade (percentages of total trade; current prices)

Despite the relatively modest adverse effect on the terms of trade the total impact of the 1973-75 international inflation was serious. It hit Poland at a very unfortunate moment. Following the December 1970 workers' riots and the change in the Party leadership a determined attempt was made to escape from the stagnation which had plagued the economy at the end of the 1960's. Gierek's development strategy was based on a concerted effort to increase at the same time consumption, in order to stimulate incentives and to secure support from the population for the new leadership, and investment, in order to modernize and restructure the economy.<sup>3</sup> A manoeuvre of this nature required considerable imports of capital which could only be obtained from the West. Both measures were expected to increase efficiency and to help to introduce the so-called "intensive pattern of development," which would make the rates of growth less dependent on increases in the quantity of inputs than on increases in their productivity. An essential feature of the strategy was a large-scale import of Western technology in the form of imported machines and equipment, licenses and various industrial cooperation agreements. To a certain extent the transfer of Western technology was accepted as a substitute for any far-reaching systemic reforms, although some improvements of the system of planning and management were envisaged and were, indeed, gradually introduced.<sup>4</sup>

The world inflation reduced the chances of success for this manoeuvre. The prices of machines and equipment increased, making the process of modernization, restructuring and expansion of the productive capacity more expensive. Moreover, the increases in the prices of fuels, foodstuffs and other materials left less foreign exchange available for the purchase of investment goods. At the same time, the recession aspect of the international stagflation made exports more difficult. Particularly adversely affected were the exports of the products of those industries which were the main recipients of imported machines and equipment.<sup>5</sup>

A difficult choice became necessary. Either the country would try to obtain even larger amounts of foreign capital than those which had been envisaged originally, increasing the level of indebtedness to a perhaps dangerous point, or the rates of growth of import had to be reduced. The second alternative could either endanger the investment programme, reduce the rates of growth of national income and delay the completion of the programme of modernization and restructuring of the economy, or lead to shortages of consumption goods. To the extent to which some import substitution was possible, it could be attempted only at the risk of creating some adverse effects. If the new tasks in this field were to be added to the already very taut investment plan, the domestically generated inflationary pressures

<sup>3</sup> Z. M. Fallenbuhl, "The Strategy of Development and Gierek's Economic Manoeuvre," "Canadian Slavonic Papers," v. XIV, Nos. 1 and 2, 1973, reprinted in A. Bromke and J. Strong (eds.), "Gierek's Poland," New York: Praeger, 1973; and "Poland in the Last Quarter of the Twentieth Century: the Economy," *Slavic Review*, v. 34, No. 4, 1975.

<sup>4</sup> Z. M. Fallenbuhl, "Recent Economic Developments in Eastern Europe," The McMaster University Conference on the Communist States, October 1975, to be published in A. Bromke and D. Novak (eds.), "The Communist States in the Era of Détente," forthcoming.

<sup>5</sup> A more detailed analysis of this problem can be found in Brown, Fallenbuhl, Licari, Neuberger, op. cit. and Z. M. Fallenbuhl, "Intégration économique en Europe de l'Est," "Revue d'études Comparatives Est-Ouet," v. 8, No. 2, 1977.

would be substituted for the foreign induced pressures. If some production and investment plans were to be altered to make room for these new tasks, shortages could appear now or in the near future which would destabilize the consumption goods market and endanger the policy of raising incomes and increasing incentives and/or create bottlenecks in the production and investment processes. If the additional domestically produced machines and equipment were technologically less sophisticated or modern, this policy could have not only a short- but also a long-run adverse impact on efficiency. It was clear that any additional import substitution in a still relatively closed economy would reduce efficiency. Moreover, this would be a withdrawal from the policy of opening up of the economy which was recognized as an essential part of the new development strategy.

There is no information on the originally planned import of capital and a difference between import and export of commodities is not, of course, equal to the import of capital and can be accepted only as a rough indicator. At current prices, the excess of import over export increased from 1.68 per cent of the value of export at first moderately to 4.27 per cent in 1971 and 8.16 per cent in 1972. It then rose dramatically to 22.23 per cent in 1973, 26.06 per cent in 1974 and 21.93 per cent in 1975 (see Table II). It appears significant that the most rapid increase occurred in 1973. The timing and the size of the increase may suggest that it was induced by the world inflation rather than planned.

TABLE II.—POLAND'S INTERNATIONAL TRADE AT CURRENT AND CONSTANT PRICES, 1971-75

	Million zloty						Rates of growth (percent)						Average, 1971-75	1975 (1970=100)
	1970	1971	1972	1973	1974	1975	1971	1972	1973	1974	1975			
Import:														
At current prices .....	14,430	16,151	19,612	26,103	34,823	41,651	11.9	21.4	33.1	33.4	19.6	23.9	288.6	
At constant prices .....	16,421	20,058	24,603	28,031	29,480		13.8	22.1	22.6	14.2	5.0	15.5	204.3	
Export:														
At current prices .....	14,191	15,489	18,133	21,355	27,625	34,161	9.2	17.1	17.8	29.4	23.7	19.4	240.7	
At constant prices .....	15,113	17,412	19,328	21,812	23,614		6.5	15.2	11.0	12.8	8.3	10.8	166.4	
Balance of trade at current prices .....	-239	-662	-1,479	-4,748	-7,198	-7,490								
Balance as percent of export (both at current prices) .....	1.68	4.27	8.16	22.23	26.06	21.93								

Note: 1 zloty=0.225 ruble. It was equal to 25 cents in 1970 and 1971, 27 cents in 1972, and 30 cents, in 1973-75. Source: G.U.S., "Rocznik statystyczny 1976," pp. 333, 334, 335.

At constant prices, the rate of growth of imports increased from 13.8 per cent in 1971 to over 22 per cent in 1972 and 1973. Import growth had to be reduced, however, to 14.2 per cent in 1974 and 5.0 per cent in 1975. The decline in the rate of growth of import, despite large imports of capital, was necessary because only much more moderate increases in export were possible to obtain. At constant prices, the rate of growth of export declined from 15.2 per cent in 1972 to 11.0 per cent in 1973. Although it increased to 12.8 per cent in 1974, it declined subsequently to 8 per cent in 1975. The very drastic decline in the rate of growth of import, which took place in that year and which brought it below the rate of growth of export, demonstrated the leaders' concern about the level of indebtedness and inability to expand export more rapidly. The rate of growth of export would have been even lower if it were not for the export of coal which expanded not only in value terms but also in quantity. This, however, made some additional investment in coal mining necessary. This requirement increased domestic inflationary pressures which were generated by an already extremely ambitious investment programme superimposed on increases in the purchasing power in the hands of the population.

Although the full impact of the world inflation was much greater than the aggregate trade figures would suggest, the transmission of external disturbances was limited because of (1) a relatively limited role of trade in the economy, and (2) the commodity and geographic structure of trade. The strength and speed of the transmission process was further reduced by (3) some systemic features which provide the first insulating layer and make it possible, at a cost of reduced efficiency, to separate domestic prices from the world prices; and (4) various government policies of non-systemic nature which were introduced for the purpose of strengthening the first insulation layer.

## *2. The Transmission Process: Limited Role of International Trade*

As the second largest CMEA country Poland has the second largest import and export among the countries of the bloc. However G.D.R., with a much smaller population, has almost the same volume of export. There is a tendency for per capita trade to be relatively smaller in larger countries, other things, particularly the level of development, being equal. The CMEA countries usually have lower per capita trade than the advanced industrial countries in the West of approximately the same size. In 1975 per capita trade in Poland was the third smallest among the CMEA countries (see Table III). Spain with slightly larger population than Poland (35,470 million) had per capita import considerably higher (U.S. \$454) but its per capita export was much lower (U.S. \$217) than in Poland.

TABLE III.—POPULATION AND INTERNATIONAL TRADE OF THE EAST EUROPEAN COUNTRIES AND THE U.S.S.R. 1975

Country	Popula- tion, millions	Imports			Exports		
		Millions U.S. dollars	Percent of world imports	Per capita, U.S. dollars	Millions U.S. dollars	Percent of world exports	Per capita, U.S. dollars
Bulgaria.....	8,720	5,309	0.6	609	4,601	0.5	528

Source: G.U.S., "Rocznik statystyczny 1976," pp. 534, 608, 609.

In all CMEA countries international trade statistics are shown in "devisa" currencies which differ from the domestic currencies. In Poland the "devisa zloty" (zld) is, in effect, a different currency than the domestic zloty (zl.). Moreover, domestic prices are isolated and differ considerably from the world prices in which foreign trade with the non-CMEA countries is calculated and from the intra-CMEA foreign trade prices in which trade with other CMEA countries is expressed. It is, therefore, meaningless to compare the value of trade, as recorded in statistical yearbooks, with the level of Net Material Product. However, the comparison of the rates of growth of trade and the Net Material Product can give some indication as to the relative role of international trade in the process of growth.

During the period 1961 to 1974 imports in constant prices grew more rapidly than Net Material Product, yielding an income elasticity of about 1.5 during the 1960's and 2 in 1972 and 1973. The rate of growth of imports fell in 1974 and 1975, so that by 1975 the income elasticity of imports was down to 0.56. (See Table IV.)

TABLE IV.—POLAND: RATES OF GROWTH OF IMPORT, NET MATERIAL PRODUCT AND INCOME ELASTICITY OF IMPORT, CONSTANT PRICES

	[In percent]							
	1961-65 average	1966-70 average	1971-75 average	1971	1972	1973	1974	1975

$\Delta M/\Delta Y \times Y/M$ .....	1.61	1.50	1.59	1.70	2.08	2.09	1.37	.56

Source: G.U.S., "Rocznik statystyczny 1976," pp. XXXV and XLV.

Calculated at constant 1971 *domestic prices* the share of import in Net Material Product increased from 19.1 per cent in 1966-70 to 26.4 per cent in 1971-75 and the share of export from 20.8 per cent to 23.1 per cent.<sup>6</sup>

<sup>6</sup> B. Wojciechowski, "Problemy importochłonności gospodarki Polski" (Import Intensity of the Polish Economy) *Gospodarka planowa*, No. 12, 1976, p. 639.

A relatively low degree of involvement in international trade is also shown by the proportion of import to the total consumption of some selected commodities or export to total output. Among the most important imports listed by the Statistical Office only 7 had the import to domestic consumption ratio exceeding 30 per cent: tea 111.3 per cent, cotton 111.0 per cent, rice 110.0 per cent, crude oil 96.9 per cent, wool 83.2 per cent, synthetic rubber 34.9 per cent and felt 31.8 per cent. Among the most important exports only 17 commodities had the export to output ratio greater than 30 per cent in 1975.

It is, however, important to remember that under a taut plan even when only a small percentage of the total supply of a particular commodity is imported, a small reduction in that import can have a considerable bottleneck effect or cause a significant shortage in the market for consumption goods. Similarly, even when only a small proportion of total output is exported, any increase in export which has to be effected in order to secure some necessary import may have the same effect on the economy.

Although the total volume of import was relatively limited a very large part of it was connected with the maintenance or enlargement of the level of production. In 1971-75 fuels, raw materials and intermediate goods for further production represented 60 per cent of total import and commodities to be used directly for investment purposes another 25 per cent. Consumption goods represented, therefore, only 15 per cent of the total imports. In this situation imports could be reduced only slightly without adversely affecting the rates of growth of the economy.<sup>7</sup>

The decline in the rate of growth in the Net Material Product which occurred in 1975 (see Table IV) was connected with a decline in the rate of import which was made necessary in order to prevent any further increase in the level of indebtedness, estimated at about \$7.1 billion at the end of that year.

### *3. The Transmission Process: Geographic and Commodity Composition of Trade*

During the period 1971-75 as a whole the average rate of growth of import was 15.5 per cent at constant and 23.9 per cent at current prices (about 54 per cent higher rate) and the average rate of growth of export was 10.8 per cent at constant and 19.4 per cent at current prices (about 80 per cent higher) (see Table II).

Calculated in current prices the CMEA share in total Polish exports and, even more so, imports declined during the 1971-75 period (see Tables III and IV). These shares are affected by the differences between the intra-CMEA prices and the world prices and they were undoubtedly understated in 1973 and 1974 when the intra-bloc prices lagged behind the rapidly increasing world prices. A part of the decline which occurred during these years and a slight increase in 1975, when the CMEA prices were revised, was due to changes in the degree of price distortions.

The extent of the distortions can be seen on the basis of the following calculations. Between 1970 and 1974 imports from socialist countries

<sup>7</sup> Ibid.

(CMEA, Yugoslavia, China, North Korea and Viet Nam) increased by 57 per cent in current prices and by 52 per cent in constant prices. Imports from non-socialist countries increased by 320 per cent during the same period, when calculated in current prices, and by 188 per cent in constant prices. In current prices exports to socialist countries increased by 70 per cent and export to non-socialist countries by 138 per cent. In constant prices these increases were 61 per cent and 41 per cent respectively. As the result, there was a considerable difference between the share of trade with one group of countries calculated in current and constant prices. In current prices the drop in the share of socialist countries in the total Polish export was from 63.9 per cent in 1970 to 55.7 per cent in 1974 and in the Polish import from 67.3 per cent to 43.4 per cent. In constant prices the share of socialist countries actually increased to 67 per cent of the total Polish export in 1974 and the decline in the share of import was only to 52.2 per cent.<sup>8</sup>

Even when measured in constant prices the increase in the share of import from the capitalist countries was quite substantial. A large proportion of Polish imports was in the form of most modern machines, which could often only be obtained from the West, especially since only from that source could they be obtained on credit. So far as fuels and raw materials are concerned, they are "hard commodities" within the CMEA region and they were, therefore, not available for the intra-bloc trade above the quotas which had been originally agreed upon, as they could easily be exported to the West at the booming world prices. There was, therefore, no geographic redirection of imports which could reduce the burden of the impact of world inflation. On the other hand, there was some geographic shift in exports in favour of socialist countries. It was probably effected in order to reduce the adverse effect of the recession aspect of world stagflation.

It was particularly important for the behaviour of the Polish terms of trade during the international fuel crisis that fuels represented a smaller proportion of total import than of total export (see Tables V and VI). On the import side the share of fuels declined from 6.1 per cent in 1971 to 5.2 per cent in 1974. However, it increased to 9.2 per cent in 1975 when the full impact of the increase in the price of Soviet oil and other fuels hit the Polish economy (in 1975 the price of Soviet crude oil increased from 16 roubles per ton to 36 roubles and in 1976 it was additionally increased by 8.5 per cent). On the export side the share of fuels declined from 14.0 per cent in 1971 to 13.5 per cent in 1972 and 12.6 per cent in 1973. It increased however to 15.9 per cent in 1974 and 20.1 per cent in 1975.

Equally important was the geographic structure of Polish trade in fuels. In 1971 and 1972 more than 90 percent of the Polish import of fuels were supplied from within the CMEA region, mainly from the U.S.S.R., while only 53.0 percent in 1971 and 56.5 percent in 1972 were exported to other CMEA countries. As the intra-CMEA prices lagged during that period behind the world prices, this geographic distribution was favourable to Poland. However, in 1974 and 1975 the CMEA share in both import and export of fuels declined, a fact which will be referred to later.

On the other hand, during the whole period 1971-75 Poland was a net exporter of fuels to the CMEA. The excess of export over import increased in 1972 and, again, in 1973. Subsequently it declined and reached a relatively low level in 1975. To the extent to which lower prices were received in the CMEA market than outside the bloc, the positive balance of trade in fuels with those countries implied a loss to the Polish economy. This loss was, however, more than compensated if the difference between the world prices and the intra-CMEA prices was approximately the same in respect of foodstuffs and, particularly, other materials than in respect of fuels. When the three groups of primary products (food, beverages, and tobacco; raw materials other than for food; and fuels) are taken together, Poland was a net importer in her trade with other CMEA countries during the period (see table VII).

TABLE VII.—TRADE BETWEEN POLAND AND OTHER CMEA COUNTRIES: NET EXPORT (+) OR NEW IMPORT (-) IN MILLION ZLOTYS

Group of commodities, SITC classification	1971	1972	1973	1974	1975
1. Food, beverages, tobacco.....	-641.8	-58.6	-92.1	-80.2	-11.5
2. Raw materials other than for food.....	-1,053.9	-1,121.5	-1,129.4	-1,243.6	-1,556.0
3. Fuels.....	212.4	308.7	384.5	380.5	56.4
Total.....	-1,483.3	-871.4	-837.0	-943.3	-1,511.1
4. Chemicals.....	207.7	292.5	371.6	273.3	215.6

Total trade with CMEA.....	-1,201.3	-427.8	-484.5	-79.6	1,195.5

Source: Tables V and VI.

No information is available on the prices of individual imports and exports. It is, however, possible to calculate average prices for the major groups. The usefulness of this exercise is obviously very limited. The average price for the entire group is affected by changes in the proportions of trade with other CMEA countries and the rest of the world, by changes within the group as to its commodity structure and by changes in the quality and other factors which affect the relative prices of individual commodities which belong to the group. For these reasons the average prices can be used even as a rough indicator only in the case of relatively homogeneous groups, such as primary products. There is no point to calculate the average prices in the case of manufactured goods (chemicals, machines and equipment, and manufactured consumption goods), where the commodity groups are usually more heterogeneous and differences in quality,

technological specifications and modernity are quite substantial and very important for prices.

From the list of the most important Polish imports some 14 items have been selected, fuels and materials, which together represented between 17 and 22 per cent of the total value of imports in the 1970 to 1975 period (at current prices) (see table VIII). Table IX presents value, quantity and unit price of these imports and in table X annual increases in quantity and in unit price are compared. The biggest increases in unit prices took place in respect of phosphorites and apatites (164.41 per cent in 1974—as this is a somewhat heterogeneous group a change in its composition could affect this increase), rye (145.57 per cent 1974), coking coal (117.54 per cent in 1975), crude oil (106.91 per cent in 1975) and natural gas (102.37 per cent in 1975). In some cases quantities imported were reduced when a big increase in the price of the commodity occurred. For example, there was a 5.01 per cent decline in the imported quantity of crude oil when its unit price increased by 25.23 per cent; 8.89 per cent reduction in the imported quantity of coking coal when its unit price increased by 117.54 per cent, and a 1.20 per cent reduction in the quantity of iron ore when its unit price increased by 35.51 per cent. Such decreases were, however, usually limited to one year only. Often increases in prices were associated with considerable increases in the quantities imported. For example, the 145.57 per cent increase in the unit price of rye in 1974 was associated with a 221.7 per cent increase in its import. Some decreases in the unit price were also associated with decreases in import (rye in 1975). To some extent the changes in the quantities could have been affected more by expectations as to the future movements of prices and changes in domestic production rather than by the current price changes. It seems, however, that on the whole there was very little freedom of manoeuvre for the planners in respect of these imports.

TABLE VIII.—POLAND: RELATIVE SHARE OF FUELS AND SELECTED MATERIALS IN THE TOTAL VALUE OF IMPORT (THOUSAND ZLOTYS, CURRENT PRICES)

Commodity	1970	1971	1972	1973	1974	1975

Source: Table VIII.

Similarly, there seemed to be very little possibility of substituting the cheaper CMEA sources of imports for the relatively more expensive sources in the rest of the world. On the contrary, the proportion supplied by the CMEA countries to the total quantity imported declined at least for one year in many cases (see table XI).

Finally, there was only a limited success with import substitution in the case of those among the selected fuels and materials which could also be produced within the country (see table XII). The proportion of import to domestic production plus import was greater in 1975 than in 1970 in the case of crude oil, natural coal gas, iron ore and wheat. The proportion was lower in the case of petroleum products, coking coal, barley and corn. It was approximately unchanged in the case of rye (which was also insignificant).

TABLE XII.—POLAND: DOMESTIC PRODUCTION AND IMPORT OF FUELS AND SELECTED MATERIALS

Table XIII presents the value, quantity and unit price of the four Polish exports of fuels: coal, coke, lignite, and petroleum products and Table XIV the balance of trade in fuels calculated at current and constant prices. In respect of fuels the difference between the balance at current prices and constant prices was favourable to Poland in all years between 1970 and 1975. If foodstuffs and materials were added to fuels the difference could have had an adverse effect. As, however, the other two groups are composed of much greater numbers of small items, it is difficult to make similar calculations.

## 4. Poland's Indebtedness

Polish balance of payments statistics are not published. From various comments which can be found in the Polish literature<sup>9</sup> it appears that the equilibrium balance of payment implies a deficit in the balance of trade which is covered by receipts from the railway transit operations (the Soviet and GDR mutual trade and the Czechoslovak access to the Baltic ports) and gifts which the population receives from the relatives who live abroad.

<sup>9</sup> P. Bożyk, B. Wojciechowski, *Handel zagraniczny Polski 1945-1969* (The International Trade of Poland 1945-1969), Warsaw 1971, pp. 248-280.

No complete information exists on the form in which Poland's borrowing took place. It seems that a substantial part was in the form of short-run suppliers' credit and this part probably creates an immediate problem. The long-term loans, mainly from the banks, were obtained largely for the expansion of the copper and coal mining. They seem to be well secured by relatively rich deposits and the efficient and modern mining technology and considerable engineering experience in this field. The loan which was obtained from Krupp during Gierek's visit to the Federal Republic of Germany for the gasification of coal is in the same category. The long-term loans from Western corporations which are granted in connection with the industrial cooperation agreements, under which parts are produced in Poland for export to other countries, are also of the same "self liquidating" nature and should not create problems under normal circumstances. A prolonged recession in the West can, however, affect the ability to repay them.

Poland's total net hard currency indebtedness increased from \$4.4 billion at the end of 1974 to \$7.1 billion at the end of 1975. The ratio of this last figure to the volume of hard currency exports represents 2:1 which is not an unduly heavy burden for a country which in 1975 was the fourth most important producer of coal in the world, the second largest producer of sulphur and the ninth largest producer of copper.<sup>10</sup>

In order to reduce any further increase in foreign indebtedness there was some reduction in the rate of investment and import in 1975. The Plan for 1976-80 envisages, although rather unrealistically, the achievement of a positive balance of trade before the end of the five year period. This objective is to be achieved by a more moderate investment policy, with new investments almost entirely restricted to export promoting or import substituting projects, relatively small increases in consumption and a considerable expansion of exports with the help of the productive capacities which were either created or modernized and expanded during the investment drive of 1971-75.

### 5. *The Insulation System*

The index of "prices of goods and services bought by the population" increased by 2.7 per cent in 1973, 6.6 per cent in 1974 and 2.9 per cent in 1975 (see table XV). These were the biggest increases ever recorded since the end of the postwar inflation of the late 1940's.<sup>11</sup> Increases in the index of "consumption goods" alone were even higher (3, 7.2 and 3.2 percent respectively). However these increases were much smaller than the increases in import prices in general (8.8, 16.9 and 14 per cent). They were particularly small in comparison with the increases in the unit prices of imported fuels and some other essential materials which were examined above.

<sup>10</sup> See Z.M. Fallenbuchl, "The Polish Economy in the 1970's" in this volume; net hard currency indebtedness as calculated by the Chase Manhattan Bank.

<sup>11</sup> Z. M. Fallenbuchl, "Economic Policy of the Period of Transition from Capitalism to Socialism," *The Canadian Slavonic Papers*, v. IX, No. 2, 1967.

Source: 1966-70 G.U.S., "Ceny, 1974" (Prices 1974), Warsaw, 1974, pp. 2-3. 1971-75 G.U.S., "Rocznik statystyczny," 1976, p. 389.

In the Soviet-type economies, even of a modified sort like Poland's in the early 1970's, there are two insulating layers between the world prices and the prices charged to the consumers. International trade organizations, and those industrial enterprises or associations (the so-called "big economic organizations" or W.O.G), which under the Polish "new economic and financial system" are allowed to get involved directly in international trade, conduct their foreign transactions in "devisa zlotys" and at prices which they actually earn or pay in the foreign markets. However, the domestic side of these transactions, the supply of goods for export and the supply of imports to the economy, takes place at the domestic zlotys and at domestic prices. Losses and extra profits resulting from the differences between the external and domestic prices are covered from or are transferred to the state budget.

An essential part of the systemic modifications which were introduced in the early 1970's was an attempt to make the foreign trade prices more meaningful for economic decisions of industrial enterprises. There were two price reforms, as from January 1st 1971 and, again, from January 1st 1975. They concerned the domestic prices of producers' goods, including fuels and materials. At the same time, however, the retail prices were kept relatively stable, and those of some basic foodstuffs completely fixed, partly for political reasons and partly to ensure that the incentive effect of higher wages is not lost. Losses resulting from this policy were, again, compensated from the state budget.

Two points should be considered in connection with this insulation system. First, the Polish index of prices of commodities bought by the population, like most official indices of this nature in practically all countries, does not show the full extent of price increases. The enterprises can introduce higher prices for "new products." Some of these products may be insignificantly modified. Others may really be of a higher quality, or a new type, but as the old ones are withdrawn from production, the consumers have no choice in this matter. There may also be some commodities which are virtually the same despite their designation as "new."<sup>12</sup> Control in these matters is very difficult. It is not only in the interest of the enterprises but also the supervising industrial ministries to achieve high proportions of "new products" as this feature is accepted as a sign of progress and there are some bonuses for such activity. Moreover, the price increases of this nature

<sup>12</sup> J. Mujzel, "Zmiany poziomu cen w gospodarce socjalistycznej," (Changes in the Price Level in a Socialist Economy), *Ekonomista*, No. 4, 1974, pp. 817-843. See also Brown, Fallenbuchl, Licari, Neuberger, *op. cit.*

increase the value of output, a welcome feature not only from the point of view of the enterprises but also the ministries and the central planning office. The authorities are interested to maintain the stability of the official price index, they therefore control the prices of those commodities that are recorded in the index and allow increases in the case of "new products."

Second, there is some real social cost to this insulation system both in the form of price distortions which tend to reduce efficiency and in the form of a burden of subsidies on the state budget. These subsidies adversely affect the financing of investment or some other economic and social activities, if revenue cannot be increased without destroying or diminishing the system of incentives.

Some indication of the degree of inflation and its nature can be obtained by comparing Net Material Product at current and constant prices, thereby getting the implicit NMP deflator. From 1971 to 1975 NMP increased from 855 billion zlotys to 1,357 billion at current and to 1,261 billion at constant 1971 prices. It may also be interesting to compare the difference between the Gross Industrial Product, Net Industrial Product and Material costs calculated at current and constant prices (see Table XVI). Material costs represented a higher proportion of gross industrial product when calculated at current than when they are calculated at constant prices. Their annual increase was higher in current prices than in constant prices and the ratio of current to constant prices was higher in every year than the ratio of current to constant prices of global and net product. There is some obvious evidence of inflation and the observations about the material costs suggest that some materials generated inflation was present. At least partly, it was caused by higher prices of imported fuels and raw materials.

## 6. Propagation

In 1971-75 fuels and materials for further production represented about 60 per cent of total Polish imports. The cost of these items must have provided, therefore, the main channel through which the

world inflation transmitted to Poland was propagated throughout the domestic economy. Increases in wages which are induced by increases in the prices of imported consumption goods and the domestically produced consumption goods using more expensive imported producers' goods can also be regarded as an element in the propagation mechanism. In Poland in 1971-75 increases in wages were, however, mainly autonomous in the sense that they were connected with Gierek's new development strategy and with the political and social pressures which appeared after the 1970 workers' riots and the change in the leadership.

In table XVII the annual rates of growth of net production in socialist industry calculated in constant prices is compared with the rates of growth of material costs and their two component parts, outlays on raw materials and outlays on fuels, and with wages, calculated in current prices. Except in 1973, the rates of growth of material costs in current prices were higher than those of net industrial production at constant prices. On the other hand, the rates of growth of wages at current prices were lower than the rates of growth of net industrial production at constant prices, except in 1975. It seems that the rates of growth of material costs were pushed up by increases in outlays on raw materials and in some years (1971, 1974 and 1975) by increases in outlays on fuels. As in 1971-74 wages were increasing by less than material costs at current prices and even less than net industrial production at constant prices, it appears that they were less responsible for inflationary pressures than increases in outlays on raw materials and fuels until 1975. A very rapid increase in wages in the socialist industry which occurred in 1975 may, however, be an indication of a price-wage spiral starting to operate.

TABLE XVII.—POLAND: TOTAL MATERIAL COSTS IN SOCIALIST INDUSTRY, OUTLAYS ON RAW MATERIALS, OUTLAYS ON FUELS, AND WAGES (CURRENT PRICES) COMPARED WITH NET PRODUCTION AT CONSTANT PRICES

	Million zloty's					Rates of change (percent)					Average 1971-75	
	1970	1971	1972	1973	1974	1975	1971	1972	1973	1974		1975
Material costs.....	773.3	854.4	949.4	1,055.2	1,242.6	1,401.5	10.5	11.1	11.1	17.8	12.8	12.7
Materials.....	623.3	688.6	769.0	856.8	1,007.7	1,136.6	10.5	11.7	11.4	17.6	12.8	12.8

Net production (constant prices)....	379.8	414.4	457.9	511.0	573.3	639.9	9.1	10.5	11.6	12.2	11.6	11.0

Source: G.U.S. "Rocznik statystyczny, 1976," pp. 150, 151.

The increases in the prices of raw materials and fuels charged to the enterprises, which are suggested by the above calculations, and even more so the increases in retail prices charged to the population shown by the official index, are smaller than the increases in the unit prices of fuels and raw materials which were examined above. This suggests that considerable subsidies had to be paid to international trade organizations and those industrial enterprises which were involved directly in foreign trade and then, again, to industrial enterprises and/or domestic trade organizations to compensate them all for their losses.

### 7. *The Price Equalization System*

In the Polish public finance system the price equalization taxes and subsidies are kept separate from other taxes and subsidies. Taxes are collected when, for example, prices paid by the procurement agencies to the producers of agricultural products are lower than the prices at which these agencies sell the products to the rest of the economy (the food industry, domestic and foreign trade, etc.). Another important example is provided by international trade. Taxes are collected when the domestic prices of imported commodities are higher than the prices of imports plus the trading margins charged by the international trade organizations, or the domestic prices of exported commodities are lower than the prices obtained in the export markets. The foreign trade prices are recalculated into the domestic currency by special coefficients which differ from the official rates of exchange, as the latter are completely artificial.

Subsidies are paid in the reverse situation. The two examples given by the Statistical Office refer, again, to agricultural prices and foreign trade prices.<sup>13</sup> They are made when the procurement prices paid to the agricultural producers are above those charged to the rest of the economy when the products are resold. In international trade they are paid when the domestic prices are lower than the prices of imports or higher than those which are received for exports.

Table XVIII shows that the price equalization taxes were growing rapidly until 1970, they were higher than subsidies, and the positive gap between the two reached its maximum in that year. At the beginning of 1971 new prices of materials were introduced. This was an attempt to introduce a greater degree of rationality into the pricing system and, among other things, to reduce the difference between the domestic and the world prices. Both price equalization taxes and price equalization subsidies declined drastically in 1971.

Another factor which had a considerable effect on the level of these taxes and subsidies was Gierek's new agricultural policy. In order to stimulate agricultural output and deliveries, substantial increases in prices were made starting with 1971 and compulsory deliveries were abolished as from January 1, 1972. The effect of this policy was a reduction in the amount of price equalization taxes. At the same time, since the workers' riots of December 1970, the prices of some basic foodstuffs have been kept constant. As a result, these prices were kept below the prices paid to the agricultural producers, the difference being covered by the price equalization subsidies.

As can be seen in table XVIII, total revenue from the price equalization taxes declined in 1971 to slightly above 50 percent of its 1970 level and the total amount of subsidies decreased from 77,369 million to 48,869 million. Net taxes (the difference between taxes and subsidies) were positive until 1971 and were growing until 1970. They declined to +0.88 percent of total budgetary revenue in 1971. Starting with 1972, negative balances appeared (net subsidies) and they were growing quite rapidly from one year to another. At least partly this situation must have been caused by the impact of world inflation, which together with the decision to keep domestic prices more stable

<sup>13</sup> See for example, G.U.S. "Rocznik statystyczny 1971," (Statistical Yearbook 1971), Warsaw 1971, pp. 601-602.

Source: G.U.S., "Rocznik statystyczny 1970" (Statistical Yearbook 1970) Warsaw 1970, pp. 536, 537; G.U.S., "Rocznik statystyczny 1976," pp. 494, 495, 496.

than the world prices, resulted in the rapid increase in the price equalization subsidies. It is interesting to note that this factor seemed to have a relatively small effect on the taxes which declined in 1973, increased in 1974, and dropped to their lowest level in 1975. In other words, the taxes collected as the result of the excess of export prices over the domestic prices of the exportable commodities were not sufficiently large to compensate for the decline in taxes which was caused by the abolishment of compulsory deliveries and the increases in the prices paid to the agricultural producers.

There were two important consequences of these developments. First, the 1971 price reform was completely frustrated. The sum of the price equalization taxes and subsidies, which may be accepted as an indicator of price distortions (or at least of some of them), declined very significantly in 1971. The sum was almost back at the same level in 1974 and, despite a new price reform which took place as from January 1st, 1975, it exceeded that level in that year. Secondly, while the net taxes represented an additional source of budgetary revenue, the net subsidies quickly became a considerable burden for the budget. In 1970 the net taxes represented almost half of total budgetary outlays on investment and major repairs. In terms of the GNP accounting they were equal to 11 percent of gross fixed investment in the economy. In 1975 the net subsidies were equal to 17.43 percent of the total budgetary revenue; they were somewhat higher than the total budgetary outlays on investment and major repairs and almost 13 percent higher than the total budgetary operating expenditures on education, science, culture and health. In terms of the GNP accounting they were equal to almost a quarter of gross fixed investment (23.20 percent). A burden of this size must have reduced the budgetary freedom of maneuver and must have made the task of increasing both investment and the standard of living at the same time more difficult. It probably contributed, together with the inefficiencies resulting from price distortions, to the government's economic difficulties which appeared in 1975 and 1976.

Only part of the increases in price equalization subsidies were caused by the world inflation. In order to estimate this part it would be necessary to know the amount of taxes and subsidies which were required in connection with foreign trade transactions. Unfortunately, no exact information on this point is available. Some rough indication may be obtained from Table XIX which presents the distribution of the equalization taxes and subsidies among the sectors of the economy. There are, however, a number of complications. (1) For the years 1969-75 "subsidies" include not only the price equalization subsidies but also the so-called "subject subsidies" which are paid to compensate the enterprises for certain lines of production which are planned to be unprofitable irrespective of the price equalization problems. To some extent these subsidies play a similar role to that of the price equalization subsidies but they are not identical. It is important to note that in the years for which separate figures of the "subject subsidies" are available (1965-1968), these subsidies were not applicable to foreign trade. It is, therefore, possible to assume that whenever there is only one figure available for the two types of subsidies in the case of foreign trade these figures represent the price equalization subsidies only.

Note: The "subject" subsidies are given separate for the year 1965-68 and marked (2), while the price equalization subsidies are marked (1). Starting with 1969 only 1 figure for the 2 subsidies added together is available.

Sources: G.U.S., "Budzet Państwa 1965-68" (State Budget 1965-68), Warsaw 1969, pp. 6 and 9; G.U.S., "Rocznik statystyczny 1970," p. 550; 1971, p. 617; 1972, p. 583; 1973, p. 604; 1974, p. 604; 1975, p. 518; 1976, p. 514.

(2) The data on taxes do not include the difference between the procurement price of potatoes which are used for the production of alcohol. The amounts are not, however, large. (3) As the result of the introduction of the new financial system as from January 1st, 1971, the sector "industry" has assumed responsibility for some "export tasks" from the sector "trade". A marked increase in the price equalization subsidies which occurred in that and in subsequent years reflects, therefore, the losses connected with the differences between foreign and domestic prices, i.e. are directly caused by the world inflation.<sup>14</sup>

(4) In the years for which separate data are provided for domestic and foreign trade the latter sector received more than 90 per cent of the combined trade subsidies (domestic and foreign trade) in 1965-68 and just under 90 in 1970. The share of foreign trade subsidies declined to 79.03 per cent in 1971, the year in which the price reform was effected. In the following year it increased, however, already to 81.32 per cent. It seems reasonable to assume that at least about 80 per cent of trade subsidies in 1973-75, the years for which only the combined subsidies for foreign and domestic trade are available, were allocated to foreign trade organizations. In 1965-68 over 97 per cent of the combined taxes were paid by the foreign trade sector. The share was 95.57 per cent in 1970. It declined in 1971, probably as the result of the price reform, but increased to 95.72 per cent again in 1972. It seems reasonable that about 95 per cent of the combined price equalization taxes were collected from the foreign trade organizations.

It is impossible to ascertain the exact amounts of subsidies and taxes which were made necessary because of the world inflation and the decision to keep domestic prices more stable than the world prices. Table XIX provides, however, an approximate indication of the size of the amounts involved.

If we assume that at least 80 percent of "trade" subsidies were paid to the foreign trade organizations and 25 percent of "industry" subsidies were connected with foreign trade transactions of the industrial enterprises, about 89,600 million in 1974 and 108,300 million in 1975 were allocated from the state budget to compensate for the difference between the prices of imports and domestic prices (assuming that no exports were sold below the domestic prices during that period). These figures should be compared with, for example, the total budgetary outlays for investment and major repairs of 111,794 million in 1974 and 120,301 million in 1975, or the total budgetary outlays on education, science, culture and health of 98,769 million and 111,224 million in these two years respectively.

Assuming that 95 percent of the combined "trade" taxes and 25 percent of the "industry" taxes were collected because the export prices exceeded the domestic prices of exported commodities, the total amounts were 40,671 million in 1974 and 39,783 million in 1975. These two sets of figures would give the net subsidies (the excess of subsidies over taxes) of 48,900 million in 1974 and 68,500 million in 1975.

There cannot be any doubt that the budgetary burden of the net foreign trade price equalization subsidies of this size must have been

<sup>14</sup> See, for example, G.U.S., *Finanse przedsiębiorstw uspołecznonych 1974* (Finances of the Socialist Enterprises 1974), Warsaw 1974, p. 12 and G.U.S., *Rocznik statystyczny 1972* (Statistical Yearbook 1972), Warsaw 1972, p. 569.

very heavy. It should be noted that until the world inflation had its impact on the prices of Polish imports and exports, there were net price equalization taxes every year. This additional source of accumulation was eliminated and replaced by a serious and growing drain on the budgetary funds. These calculations also suggest that a large part of the price distortions which increased, and frustrated the 1971 and 1975 price reforms, were caused by the world inflation and attempts to protect the economy from its direct effect.

### *8. Conclusion*

Poland provides a good example of a country which attempted to insulate the domestic economy against the impact of world inflation and to contain the external disturbances as much as possible at the first insulation layer. This was done not by a revision in the exchange rate, or coefficients of currency exchange, but by price equalization subsidies. In order to strengthen the insulation layer some systemic reforms were stopped and even reversed. For example, various funds which had been accumulated by the economic organizations were frozen and the direct link between their performance and the ability to improve remuneration and working conditions, or to effect some minor investment, was cut off.

However, even in Poland, where there was a somewhat limited transmission because of the limited role of international trade and the specific commodity and geographic composition of trade, the first insulation layer was unable to stop the whole impact. Some propagation took place, mainly through increases in the costs of fuels and materials. The second layer was also utilized. Some impact on the retail prices was, however, recorded by the official price index, and the actual increases were probably still higher. Some of them were likely classified as prices for new products. In the case of the prices for basic foodstuffs the leaders were forced by the opposition of the population to withdraw their attempt to pass some of the price increases to the retail price level. There the pressure was mainly, but not exclusively, of internal origin. To the extent to which the domestic production of fertilizers was supplemented by imports and the production of meat, the most important commodity in this group, was based on imported feeds, the effect of the propagation of the external disturbances was also present.

On the other hand, considerable improvements in wages, pensions and welfare payments were allowed for internal policy reasons. They should, therefore, be regarded as autonomous movements from the point of view of the impact of international disturbances.

It seems that the economy had to pay a high price for the policy of containing world inflation. There was a rapid increase in the budgetary burden of price equalization subsidies, which reduced its ability to invest and/or to expand other budgetary outlays. There was also an increase in the degree of price distortions, which must have had an adverse effect on the overall economic efficiency. It is, of course,

difficult to say to what extent the disappointingly small success in expanding exports to the advanced countries in the West, which resulted in the underfulfilment of the export plans in this direction and the overfulfilment of the plans for export to other C.M.E.A. countries, was caused by the loss of efficiency resulting from the choice of the strategy of containing world inflation. It is, however, possible to expect that there was some connection.

### III. THE CASE OF YUGOSLAVIA

#### 1. *An Overview of Some Important Characteristics of Yugoslavia's Foreign Trade*

Before analyzing the impact of the 1973-74 worldwide inflation of commodity prices on Yugoslavia, it is necessary to examine briefly some of the major characteristics of Yugoslav foreign trade. The first thing to note is the relatively high degree of openness of the Yugoslav economy. During the 1971-74 period, imports averaged about 29 percent of gross domestic material product.<sup>15</sup> Trade ratios of this magnitude are characteristic of market economies of similar size and development level, such as Greece and Portugal, where the comparable figures were 22 and 34 percent during the same period.<sup>16</sup> Unfortunately, because of differences in domestic and foreign prices in planned economies, it is impossible to use trade ratios to compare the degree of openness in Yugoslavia and in similar East European economies. Indirect comparisons based on figures for per capita imports, and still subject to severe price and exchange rate limitations, indicate that Yugoslavia with per capita imports of \$361 in 1975,<sup>17</sup> is more dependent on trade than Romania, comparable to Poland with per capita imports of \$369, and less dependent than all the other East European countries.

The second thing to note about Yugoslavia's foreign trade performance is the persistence of a substantial balance of trade deficit as the figures in table XX reveal. During the 1971-75 period, the trade deficit ranged between a low of 17 billion dinars in 1972 and a high of 63 billion dinars in 1974. These overall figures mask the specific geographical pattern of the deficit. The major share of the deficit arises in trade with western industrial countries. For example, in 1973, 1974, and 1975, the share of the deficit arising in this segment of trade was 74, 75 and 89 percent, respectively. In contrast, trade with centrally planned economies is balanced, with only minor net surpluses or deficits in each year. The same conclusion applies to trade with developing countries. Only in 1974 and 1975 did the trade deficit with these countries increase sharply due primarily to the oil price rises. Even then, the magnitude of the deficit was small relative to the deficit realized in trade with the industrial West.

<sup>15</sup> This figure is calculated from data in Table A, Appendix, *O.E.C.D. Yugoslavia*, 1976.

<sup>16</sup> These figures are calculated from data in I.M.F. *International Financial Statistics*, February, 1977.

<sup>17</sup> This figure is calculated from data in Table K, Appendix, *O.E.C.D. Yugoslavia*, 1976.

The trade deficit in Yugoslavia is offset to an important extent by two items in the invisibles account: earnings from tourism and remittances from workers temporarily employed abroad. Between 1971 and 1975, receipts from these sources equaled about 63 percent of receipts from total merchandise exports. As a result of earnings from these two items, the current account deficit has been significantly smaller than the balance of trade deficit as the figures in table XXVI illustrate. Because of the importance of these items in Yugoslavia, they serve as potential channels by which international economic disturbances influence the domestic economic situation. For example, the stagnation in Western Europe in 1974-75 encouraged a marked slowdown in the annual rate of growth of tourism earnings from an average of 29 percent in 1971-73 to an average of 8.4 percent in 1974-75; and in the annual rate of growth of worker remittances from an average of 39.2 percent in 1971-73 to 11.2 percent in 1974-75. Slowdowns in receipts from these sources exacerbated the problem of financing the growing trade deficit in these years. In addition, depressed conditions in Western Europe stemmed the net outflow of Yugoslav workers and generated a net return of about 50,000 workers per year in 1974-75.<sup>18</sup> The net inflow of labor, of course, worsened the unemployment problem in Yugoslavia, and provided yet another channel whereby the western stagnation influenced domestic economic conditions.

Because of the commodity composition of Yugoslavia's foreign trade, described in table XXI, the worldwide inflation in 1974 caused a net deterioration of about 11 percent in Yugoslavia's net barter terms of trade. This overall deterioration was the result of an adverse shift in the terms of trade for fuel and raw materials, products for which Yugoslavia is a net importer. As the data in table XXII reveal, the terms of trade worsened noticeably for these product categories and for food in 1974. Only in chemicals, processed materials, and machinery and equipment did the terms of trade improve, but not sufficiently to offset an overall deterioration.

<sup>18</sup> This figure is reported in The Federal Planning Office document, "Analytical Basis for the Documents of the Social Plan of Yugoslavia from the Period 1976-80," Belgrade, 1976. Higher estimates of a net inflow of 100,000 workers per year have been reported in *Ekonomika Politika*, May 17, 1976.

Source: SZS, "Statistički Godišnjak, 1976," pp. 232-233.

The domestic impact of the worldwide inflation was somewhat moderated by the fact that over half of Yugoslav imports and exports consist of machinery and other manufactured products whose world prices rose at a slower rate than did fuel and material prices in 1974. The total of the food, raw material, and fuel categories accounted for over one-third of imports only in that one year, when the prices of these goods rose dramatically. Before 1974, and again in 1975, these categories accounted for about 30 percent or less of total imports.

Machinery and other manufactured goods play an even more dominant role in Yugoslav export trade. In every year between 1971 and 1975, these two categories accounted for about two-thirds of Yugoslav exports. In contrast, raw materials and fuels amounted to only about 10% of total exports. When this is combined with the fact that total Yugoslav exports are considerably smaller than total imports, it becomes clear why Yugoslavia was not able to gain a net benefit from commodity price increases in world markets.

Given the significant balance of trade deficit ranging from a low of 44.5 percent to a high of 97.7 percent of Yugoslav exports, (as shown in table XX) a rise in world market prices of the 1973-74 magnitude would have created havoc with the Yugoslav balance of trade, even if both import and export prices had risen at the same rate leaving the terms of trade unchanged.

The geographical redistribution of Yugoslav exports and imports was very similar to that of Poland during the 1973-75 period. Although Yugoslav imports from socialist economies increased by an average annual rate of about 25 percent between 1971 and 1975, they remained approximately the same share of total imports (see table XXIII). In 1974, when a partial reorientation towards socialist markets might have been anticipated, their share in the total value of Yugoslav imports actually declined reflecting the more rapid growth of imports in value terms from the LDC's and, to a lesser extent, from western markets. In contrast to imports, exports to planned economies actually increased as a share of total exports in 1974 and again in 1975, largely in response to stagnation in traditional western markets for Yugoslav exports.

Source: Table L, appendix, OECD, "Yugoslavia, 1976."

The data in table XXIV indicate the important role played by CMEA countries in Yugoslav imports of some of the fuels and raw materials whose prices rose sharply on world markets in 1974. Yugoslavia depended on CMEA sources for dominant shares of its imports of coal, coke and chemical fertilizers and for significant shares of its imports of crude oil and cotton fiber. As an observer rather than a full member of CMEA, Yugoslavia was unable to purchase these imports at intra-CMEA prices which lagged behind world prices. Nonetheless, the figures in table XXIV suggest that the prices which CMEA sellers charged Yugoslav buyers did not rise nearly fast as the prices charged by non-CMEA sellers for coke and cotton fiber. In addition, the CMEA price for coal exports to Yugoslavia did not rise as fast as the world price of coal, as measured by the cost per short ton of

U.S. coal (which rose by about 70 percent in 1974). On the other hand, CMEA and non-CMEA prices for oil and fertilizer imports by Yugoslavia increased at roughly the same rate.

TABLE XXIV.—YUGOSLAVIA: IMPORTANT RAW MATERIAL AND FUEL IMPORTS IN 1973 AND 1974

Source: "Statistika Spoljne Trgovine SFR Jugoslavije, 1973 and 1974."

These results suggest that at least for imports of coke and cotton fiber, and possibly also for imports of coal, Yugoslav dependence on CMEA sources acted to mitigate the effects of the worldwide commodity price inflation in 1974. Despite the lower rate of inflation of CMEA prices for these commodities, however, the CMEA share in the total volume of Yugoslav imports remained roughly constant in 1974. Only in the case of coal did the CMEA share increase noticeably from 92.5 percent in 1973 to 100 percent in 1974. In evaluating the evidence presented in table XXIV, we must be careful to take account of possible differences in the quality or the nature of imports from the two sources. These differences cannot be captured by the comparison of unit values presented in the table.

As the data in table XXIII reveal, the most marked alteration in the geographical composition of Yugoslav trade during the 1971-75 period was the increase in the share of Yugoslav exports sold in eastern markets in 1974 and 1975. Faced with declining markets in Western Europe, caused partly by the oil-induced recession and partly by the ban on Yugoslav exports of beef to the EEC in 1974, Yugoslav exporters sought out substitute buyers in Eastern Europe. As a result, exports to planned economies increased sharply by 62.9 percent in 1974 and by another 21.7 percent in 1975. This temporary redirection of export trade was undoubtedly instrumental in offsetting some of the impact of declining export demand in Western Europe, but it did nothing to solve the problem of a growing trade deficit with that area.

## 2. The Transmission Process in Yugoslavia

From the data presented in table XXII, it is clear that the world-wide commodity inflation caused dramatic increases in Yugoslavia's export and import prices beginning in 1973. The transmission process focuses on how these increases worked through the foreign trade and exchange network to cause changes in domestic wholesale prices and changes in the quantities of imports and exports. Therefore, a study of the transmission process naturally begins with an analysis of Yugoslavia's foreign trade and exchange systems.

Most East European socialist economies attempt to insulate their domestic wholesale prices from changes in world prices by using a system of taxes and subsidies to divorce domestic and international prices, and by negotiating long-term trade agreements at fixed prices (generally an average of world prices during past years). In contrast, Yugoslavia not only fails to divorce domestic and international prices, but actually facilitates through its price control policy the process by which world price increases cause domestic price increases. According to this policy, the domestic prices of a significant number of commodities are administratively and automatically linked to international prices by formulas which use world prices, the prevailing foreign exchange rate, and existing taxes and subsidies to calculate the appropriate domestic wholesale (producer) prices.<sup>19</sup> By using formulas of this type, the Yugoslav authorities have, in effect, replaced the market mechanism by a system of controls designed to keep domestic relative prices in line with world relative prices. In this way, they have made the transmission mechanism operate even more effectively than it would under normal market conditions.

In the Yugoslav system, as in other market economies, the foreign exchange rate is a crucial link between domestic and international prices. As long as the exchange rate remains fixed, changes in international prices lead directly to corresponding changes in the domestic prices of tradeable goods. During the 1973-75 period examined in this study, the dinar exchange rate was allowed to fluctuate within limits established by the Yugoslav National Bank. Because these limits were fairly narrow, the exchange rate was relatively constant for protracted periods of time. Changes, when they occurred, tended to be large and the result of policy decisions, such as the decision to allow the dinar to depreciate by about 8 percent relative to the dollar in October 1974. This devaluation was one of the many policy responses of the Yugoslav government to the deterioration in the balance of payments which began in mid-1973.<sup>20</sup> The devaluation itself led to further increases in the domestic wholesale prices of tradeables which had already increased in response to rising world prices at constant exchange rates.

Because foreign trade decisions in Yugoslavia are largely decentralized and within the competence of individual enterprises, changes

<sup>19</sup> An example best illustrates how the administrative links between domestic and world market prices operate. In a 1973 social agreement on prices of non-ferrous metals and products, it was determined that domestic prices be set equal to average world futures prices quoted during the last six months, evaluated at the official exchange rate and increased by 3 percent due to tariff protection. See I. Karli, "Neki aktuelni problemi sistema i politike cijena," *Ekonomski Prehled*, 8-9, 1974, pp. 603-632.

<sup>20</sup> The role of devaluation as well as other more technical questions concerning the impact of world inflation on Yugoslavia is discussed in a paper by E. Neuberger and L. Tyson entitled, "Can a Rise in Import Prices be Inflationary and Deflationary: The Case of Yugoslavia." Stony Brook Working Paper number 175 April 1977.

in exchange rates, taxes, subsidies, and domestic and international prices influence foreign trade activity. The government attempts to guide decentralized foreign trade decisions by a number of selective policy tools. In addition to export subsidies (usually in the form of tax reductions or tariff rebates), the Yugoslavs have introduced retention quotas, which allow enterprises to retain a certain portion of their foreign exchange earnings for their own use and preferential rediscount credits to finance the production and sale of exports. On the import side the Yugoslavs have employed tariffs, surcharges, quantitative restrictions, and foreign exchange quotas to limit imports, and selective credit policy to finance the imports of favored commodities.

Government trade and exchange policies of this type are aimed at keeping enterprise decisions, which are based on profitability criteria, consistent with broader social goals. They are generally not designed to prevent the transmission of world market price changes to domestic prices, but they can be used for this purpose under extreme circumstances. For example, in 1974, import duties and import taxes on oil, gas, ferrous metallurgy products and other raw materials were lowered in an attempt to reduce the impact of the rise in world prices on domestic wholesale prices. Government policies can also be used to induce or necessitate changes in the quantities of imports and exports in response to world market conditions. Thus, beginning in 1974 and continuing through 1975, the Yugoslavs increased import taxes, and tightened quantity and foreign exchange quotas to reduce the imports of certain commodities and to stem the growing trade deficit.

### 3. *The Propagation Process*

The Yugoslav foreign exchange and trade systems allowed increases in world prices to cause increases in the domestic wholesale prices of tradeable goods in 1973-75. The magnitude of these "first-round" domestic price increases is suggested by the figures on producer prices contained in table XXV. The propagation process focuses on how these price increases worked through the consumer and producer trade and production networks and the labor market to raise retail prices and wages.

Because the worldwide inflation was largely concentrated in the prices of raw materials and fuels, which are important inputs in production, a crucial step in the propagation process was the pass-through of production costs to the wholesale prices of final products. The link between rising input costs and rising selling prices in Yugoslavia operated through the price control system which covered about 80% of industrial products and most basic food items in the 1973-75 period. This system required that enterprises wishing to raise prices obtain approval from the competent price control agency.<sup>21</sup> Two of the key criteria used by these agencies in deciding whether to approve a price increase were increases in world market prices and increases in production costs. Between 1973 and 1975, when input prices rose dramatically as a result of the worldwide commodity inflation, this price

<sup>21</sup> Federal price control agencies had jurisdiction over major agricultural product prices, most industrial prices, and rail freight rates; republics controlled electricity rates, rail and bus rates, and construction materials; communes controlled rents, community utilities, and retail food prices. Thus, it was the federal and republican control agencies that determined the effectiveness of the propagation mechanism and the impact of increases in the wholesale prices of imports on the prices of other goods.

control system allowed cost increases to be passed on quickly to the wholesale prices of many domestic products. Since retail margins, transportation costs, and turnover taxes remained more or less unchanged for most products, increases in wholesale prices led to proportionate increases in retail prices. This conclusion is consistent with the data in table XXV which indicate that wholesale and retail prices for industrial commodities increased equally by 29.9 percent in 1974.

TABLE XXV.—YUGOSLAVIA: PRICES AND WAGES, 1971-76

	Annual rates of growth (percent)

<sup>1</sup> Rate of growth measured from January-July 1976, over the same period of the previous year; figures calculated from data in "Indeks," August 1976, p. 34.

<sup>2</sup> Year-to-year annual growth rates calculated from data in tables 122-2 through 122-6, "Statistički Godišnjak, 1976." <sup>3</sup> January-May 1976, relative to same period of previous year; figures calculated from data in "Indeks," August 1976 p. 43.

So far the argument indicates why wholesale and retail prices of tradeables and of those goods which used tradeables as productive inputs rose in 1974. However, this argument does not in itself imply that these individual price increases led to an increase in the aggregate price level or to an increase in the overall rate of inflation.<sup>22</sup> In fact, under conditions of constant or constantly growing nominal aggregate demand, price increases in certain products or sectors should have been offset by reductions in prices or rates of inflation in other commodities, so that the aggregate price level or the aggregate rate of inflation remained constant. These conditions were not satisfied in Yugoslavia just as they were not satisfied in many market economies, because of the presence of nominal and real wage rigidities and consequent price rigidities. These rigidities were rooted in the institutional system of wage and price determination which allowed both prices and wages to be insensitive to conditions of excess supply. The characteristics of this system are discussed in detail elsewhere and need only be summarized here.<sup>23</sup> The majority of industrial commodities in Yugoslavia have "administered" prices set on the basis of cost markups which are only mildly sensitive to the state of product demand. Wages, an important component of production costs, tend to be insensitive to conditions of excess labor supply and tend to be responsive to changes in inflationary expectations because of the wage setting rules of individual self-managed enterprises.

As argued in a previously cited paper,<sup>24</sup> there exists evidence of

<sup>22</sup> For the possible relationships between import-induced sectoral price increases and the aggregate rate of inflation, see M. Miller "Can a Rise in Import Prices be Inflationary and Deflationary: Economists and the U. K. Inflation," "American Economic Review," September, 1976, pp. 507-508.

<sup>23</sup> See L. Tyson, "The Yugoslav Economy in the 1970's: A Survey of Recent Developments and Future Prospects," in this volume.

<sup>24</sup> Neuberger and Tyson, *op. cit.*

downward nominal and even real wage rigidity in Yugoslavia. In the presence of such rigidity, the monetarist conclusion that import induced domestic price increases in some commodities will not cause an increase in the overall rate of inflation must be rejected in favor of the Keynesian conclusion that these increases will generate aggregate inflation.<sup>25</sup> This conclusion holds, as long as there is no offsetting decline in aggregate demand, either policy-induced or caused by other factors.

The existence of wage and price rigidities, and the absence of an offsetting decline in aggregate demand, caused the import-induced price increases in certain commodities to foster an increase in the overall rate of inflation in Yugoslavia in 1974, as the data in table XXV suggest.

In analyzing real wage resistance, it is essential to specify the price index according to which real wage calculations are made. In Yugoslavia, as in many Western market economies, workers tend to regard the cost-of-living index as the appropriate deflator.<sup>26</sup> Since this index includes services and nontradeables, especially many food items not involved in Yugoslav foreign trade, there is no reason to anticipate a one-to-one relationship between increases in wholesale prices or even retail prices caused by changes in world market prices and increases in the cost-of-living index. In fact, in 1974, because of a good harvest, and partly because of a relatively moderate increase in the prices of many services, the cost of living increased by 20.5 percent, as compared to a 29.9 percent rise in both the wholesale and retail price indexes for industrial goods. Thus, the choice of a deflator is significant, and worker pressure for increases in nominal wages was somewhat less intense in 1974, than it would have been if the wholesale or retail price index had been considered the relevant one.

Counteracting this moderating trend was a rapid growth of nominal wages by 28 percent in 1974, to make up for stagnant and declining real wages in 1972 and 1973, caused in part by poor harvests, and in part by a partial wage freeze in 1973.

#### 4. *The Containment Process*

The containment process refers to all of the policies and systemic changes designed to moderate or impede the transmission and/or propagation of world price increases. In Yugoslavia in 1974, the containment mechanism was extremely weak, as a result of three elements in the Yugoslav economic strategy for that year. First, as noted above, Yugoslav leaders were committed to a policy of linking domestic prices of tradeables to world prices in order to achieve a rational domestic price system. A containment policy aimed at interfering with the transmission process was clearly at odds with this objective. Second, from mid-1973 to mid-1975, an expansionary macroeconomic policy was pursued to foster economic growth and employment. The firm commitment to this policy made it impossible to introduce demand

<sup>25</sup> The Keynesian model also implies that the import price increases will have an aggregate contractionary effect on the economy if they cause a deterioration in the overall terms of trade and a resulting real income loss. This occurred in Yugoslavia in 1974, and is discussed in our paper cited above.

<sup>26</sup> In the U.K., however, wages of about one third of the labour force were tied to the retail price index, according to Miller, *op. cit.*, p. 501.

reducing measures to control domestic inflation.<sup>27</sup> Finally, because of the stagnation of real wages in 1972 and 1973, the Yugoslav government was reluctant to adopt a strict incomes policy to control inflationary pressure at the expense of labor incomes.<sup>28</sup>

Under these circumstances, the Yugoslavs were able to introduce only relatively weak containment policies, such as the reductions in tariffs discussed above, and small reductions in the turnover taxes on a few commodities, including gasoline, other fuel products, and a few basic consumer goods. These measures were too weak and too isolated to have any major impact on the aggregate rate of inflation.

The results of the Yugoslav economic strategy in 1974 are evident from the data in tables XXV and XXVI. First, the primary objective of achieving a rapid growth rate was realized in 1974 and through the first half of 1975. Second, the overall rate of inflation increased sharply between 1973 and 1974. Third, the combination of rapid inflation and rapid growth along with a deterioration in the aggregate terms of trade and stagnating demand in world export markets—conditions over which the Yugoslavs had little control—caused a sharp deterioration in the balance of trade and consequent reserve losses.

TABLE XXVI.—YUGOSLAVIA: INDICATORS OF MACROECONOMIC PERFORMANCE, 1971-1976

<sup>3</sup> Figures calculated from data contained in various issues of "Indeksi"; 1976 is a January-September estimate of growth over same period of previous year.

<sup>4</sup> IMF, "Balance of Payments Yearbook."

<sup>5</sup> Estimate, January-September 1976, cited by B. Sefer in an interview with "Borba," Oct. 27, 1976, p. 9.

In October 1974, the dinar was devalued in an attempt to moderate the trade deficit. In addition, as was noted earlier, more restrictive import controls were introduced. In response to these policy measures, the trade deficit declined somewhat between the second half of 1974 and the first half of 1975, but its absolute magnitude remained intolerable. Moreover, the current account balance failed to improve sufficiently, because of slowdowns in the growth of earnings from remittances and from foreign tourism caused by the recession in Western Europe. Therefore, reserve losses continued and Yugo-

<sup>27</sup> In fact, to the extent that it was necessary, the Yugoslavs made special efforts to counteract the contractionary effects on the money supply induced by the loss of foreign exchange reserves. They also tried to offset the depressing effects of the real income loss occasioned by the deterioration in the terms of trade. For more detail on these policy efforts see the paper by E. Neuberger and L. Tyson, *op. cit.*

<sup>28</sup> After 1971, enterprise wage decisions were guided by annual incomes policies, which took the form of intra-republican and inter-republican agreements that constrained the distribution of enterprise income between personal incomes and enterprise savings. These agreements were not designed primarily to control the absolute wage level or its rate of growth but to set acceptable limits to inter-enterprise wage differentials. Incomes policies of this variety probably reduced aggregate wage inflation somewhat, but they were certainly not strong enough to control the 1974 inflationary pressure.

slavia's net long-term indebtedness to the rest of the world climbed sharply. Over the 1974-75 period, the total loss in reserves mounted to \$552 million, and the total increase in long-term indebtedness to \$1,319 million. In light of these developments, the Yugoslav leaders reluctantly adopted contractionary aggregate demand policies in the second half of 1975 to cut import demand and to reduce the trade deficit. As the data in table XXVI reveal, the attempt was successful but only at the expense of a marked slowdown in real growth rates. Ultimately, then, the worldwide inflation of fuel and raw material prices, the stagnation in Western Europe, and the adverse shift in the terms of trade forced the Yugoslav leaders to sacrifice their expansionary output and employment goals, at least temporarily.

### 5. *Concluding Comments*

The Yugoslav experience during the 1973-75 period clearly attests to the trade-offs between price stability, employment and output growth, and external balance, which exist in a market system with wage and price rigidities. In such a system, import induced price increases generate overall inflationary pressure as long as the government fails to adopt offsetting contractionary aggregate demand policies. Since wage and price rigidity is at the root of the conflict between inflation and output growth, an incomes policy suggests itself as a useful addition to government policy instruments. An effective incomes policy in 1974 would have undoubtedly reduced the inflationary impact of the import price increases at given levels of output and employment. This is not to say, however, that such a policy could have eliminated these effects completely. Given the magnitude of the import price rises in 1974, and the primary nature of the particular commodities involved, there was no way for the Yugoslavs to offset completely the import induced inflation. The use of either an incomes policy or a contractionary fiscal and monetary policy sufficient to accomplish this task would have required a politically unacceptable contraction in employment, output, and real incomes.

## IV. COMPARISONS AND CONCLUSIONS

### 1. *Systemic Differences*

#### 1A. SYSTEMIC DIFFERENCES IN THE FOUR PROCESSES OF IMPACT MODEL

The first major difference between Yugoslavia and Poland is that the former does not try to insulate its domestic prices from world market prices during the transmission stage. Although both countries are committed to improving the rationality of their price systems, primarily by allowing domestic price relationships to correspond more closely to those on world markets, the Yugoslav commitment has been long lived and implemented to a large extent.

In Poland under the "new financial and economic system" the world prices were allowed to have a direct effect on the financial results of economic organizations and, therefore, on their decisions, through the newly established "transaction prices" (the prices actually received or paid in foreign trade multiplied by coefficients of currency exchange differentiated according to the main trading regions). The

world inflation created a powerful and entirely unexpected impact on the financial results of some economic organizations. The leaders reacted by withdrawing some essential features of the newly established parametric system of planning in order to insulate the economy from these external disturbances.

Ironically, the 1973-75 world shift in relative prices in favor of fuels, materials and food on world markets corresponded exactly to the type of shift that the leaders of both countries contemplated in order to make their price systems more rational. Thus, if the Polish leaders had followed the Yugoslavs in merely permitting world relative price trends to guide domestic relative prices by allowing the transmission mechanism to function, then their goal would have been accomplished. However, there existed a very serious conflict between this goal and twin desires to insulate the domestic economy from external shocks and to avoid political repercussions from raising prices of basic food and other commodities which had been kept at artificially low levels to enhance the real purchasing power of the population.

In Yugoslavia, as discussed above, the price control system acts as a direct link between changes in world prices and domestic prices. In Poland this link is severed by the price equalization system.

To the extent that the changes in world prices are not completely insulated at the transmission stage in Poland, the resulting impact on domestic producer (wholesale) prices of tradeables will have further potential impact during the propagation stage. The existence of price and wage controls, and the operation of the whole planning mechanism that causes irrational prices to have less significance than they do in a market system, act to impede the speed and magnitude of changes in domestic retail prices and wages.

By contrast, in Yugoslavia neither the existing price controls nor the incomes policies were able to prevent the propagation of externally induced inflation, given that the Government was unwilling to bear the employment and output sacrifices of cutting aggregate demand. Thus, the propagation process, as well as the transmission process, was much more effective in Yugoslavia than in Poland.

Moreover, the unwillingness of Yugoslav leaders to alter significantly either the economic system or the short term growth policy, precluded the possibility of adopting any truly effective containment measures.

In Poland the containment mechanism involved (1) a marked increase in the use of price equalization measures, particularly subsidies which expanded rapidly; (2) some upward adjustment of the prices of centrally allocated producers goods as from January 1, 1975; (3) relatively limited increases in retail prices (some hidden in the form of "prices for new products", others open—here the leaders were prepared to go even further by attempting to increase the prices of foodstuffs, which had been frozen since the December 1970 workers' riots, but were forced to leave these prices unchanged because of an open opposition by the population), and (4) a partial withdrawal of systemic changes. The first two insulation layers were, therefore, considerably strengthened. On the other hand, there was no attempt to utilize the third layer. Wages and other incomes (incomes of agricultural population, pensions and welfare payments) were allowed to increase well above the planned increases. This can be explained by relative insecurity of the leadership which had come to power as

the result of riots over price increases and because higher wages and other incomes were an essential part of the new development strategy.<sup>29</sup>

It is essential to bear in mind that despite the differences in the transmission, propagation and containment processes, and the much greater tendency by some countries to insulate the domestic economy from external disturbances, no country is left unaffected by important changes in the world economy. For example, both countries faced a slowdown in Western demand for their exports due to the oil induced recession in the West. In addition, Yugoslavia was forced to absorb a real income loss due to the deterioration in the terms of trade.

Poland, because of her position as an important exporter of coal, suffered only a minor deterioration in the terms of trade in 1973 and 1974.

Systemic differences influenced the manner in which this real income loss manifested itself and in its distribution among different population groups. In Yugoslavia, the distribution of the loss was largely determined by the uneven impact of open inflation. In Poland, there was no dramatic terms of trade loss, so the leaders were faced primarily with the problem of how to deal with the deterioration in the balance of trade.

#### 1B. ROLE OF EXCHANGE RATE IN THE TRANSMISSION PROCESS

Since the transmission process consists of the link between foreign prices and domestic (wholesale) producer prices of tradeables, it is clear that it must be mediated by the exchange rate between domestic and world currencies. The nature of the transmission process thus depends in part on the exchange rate system. In Yugoslavia, the official unitary exchange rate is in fact the rate that is relevant for the transmission process. On the other hand, in Poland, the official rate is not relevant, and it is the multiple, implicit (shadow) rates that operate in translating foreign prices into domestic prices. There exist separate rates for trade with the West and trade with CMEA, and these rates depart significantly from the official rates. In addition, there exist various coefficients for specific commodity groups, making the exchange rate truly multiple.

#### 1C. OPEN VERSUS HIDDEN INFLATION

In dealing with the existence of inflationary pressures in the case of Poland, we must first discuss the problem of hidden inflation.

Open inflation may be observed in an increased general price level as measured by consumer price indices, GNP deflators, or other similar indices. Hidden inflation is much more difficult to discover, measure, or even define. We may differentiate among these different manifestations of hidden inflation, all of which occur to varying degrees in East European countries: repressed inflation, pseudo-product differentiation, and forced substitution. Repressed inflation exists when price controls and/or subsidies and taxes are used to prevent prices from changing despite pressures for price changes. In this case, shortages or undesirable resource reallocations are the price paid for price stability. Pseudo-product differentiation exists when firms introduce

<sup>29</sup> See Fallenbuehl, "The Polish Economy in the 1970's" in this volume.

new products which differ from existing products only in superficial ways, but are sold at substantially higher prices. This is really equivalent to open price inflation as far as the impact on consumers is concerned, but it does not show up in the price statistics since prices of old products have not changed, and it is therefore hidden. Forced substitution is a variant of pseudo-product differentiation, where no new products are introduced, but all of the lower price products in any given line are taken out of production or are no longer imported, and the consumers are forced to buy the higher price products whether they prefer them or not. In this case, the higher price products may actually be of better quality and provide greater utility, but the fact that the consumers did not shift their purchases to these higher price products before shows that the increased utility was not sufficient to compensate for the higher price. Thus, all three of these categories of hidden inflation lead to effects similar to those of open price increases. In view of this, one could define inflation, or rather the existence of inflationary pressures, in a very general way, to cover all these various types of effects that take place under different economic systems. We may consider inflationary pressures to be present whenever there exists a set of conditions that result either in actual increases in the general price level (open inflation) or that lead to significant resource reallocations or redistributions of goods if changes in general price levels are prevented from taking place (hidden inflation).

## *2. Discussion of Policies and Outcomes*

### 2A. INFLATIONARY PRESSURES

All East European countries experienced significant externally generated inflationary pressures in 1973-75. In addition, in the case of Yugoslavia and Poland there were significant internally generated inflationary pressures prior to 1973 (see respective country studies). There exists no strong consensus among Yugoslav economists and government leaders or foreign students of Yugoslavia on the relative importance of the different factors contributing to domestic inflation. The two major domestic factors thought to contribute to Yugoslav inflation were excess demand fueled by expansionary monetary policy, and wage push pressures. These two domestic factors interacted with the externally generated inflationary pressures to bring about a rise in industrial producer prices of about 30 percent in 1974.

There seems to be a consensus among Polish economists that the domestically generated inflationary pressure was much stronger than the impact of world inflation. This internal pressure was associated with the new development strategy which envisaged increases in both investment, in order to modernize and restructure the economy, and consumption, in order to secure meaningful material incentives, with the help of foreign borrowing of capital. Both, investment and consumption, increased however much more rapidly than had been planned. Although foreign borrowing also exceeded the originally expected level, it was still insufficient to eliminate the whole domestically generated inflationary pressure.

## 2B. IMPACT OF EXPANSIONARY POLICY AND TERMS OF TRADE SHIFTS

In the case of both Poland and Yugoslavia, the mid 1973 commodity price inflation hit the economy at an unfortunate time. It interfered with Gierek's development strategy and systemic changes outlined above and with Yugoslav efforts to stimulate the economy without incurring an unsustainable balance of payments deficit. Even in the absence of the dramatic world price changes, one would expect to observe an increase in the trade deficit of both countries since their growth strategy required increased imports of raw material and capital inputs, without a comparable rise in exports. As shown in Tables II and XX imports in real terms increased faster than exports in the expansionary phase that began in 1973 in Yugoslavia and 1971 in Poland. The rise in international prices amplified the burden of the existing trade deficit. In the case of Poland where the terms of trade were relatively constant, even if exports and imports had been constant in real terms, higher import and export prices would have resulted in a larger absolute deficit. As it was, the combination of a more rapid growth of imports than exports, and a rise in the prices of both resulted in much larger deficits. As shown in Table II, the trade deficit as a percent of exports rose sharply from 8 percent in 1972 to 22 percent in 1973.

In the Yugoslav case, the situation was aggravated by the unfavourable change in the terms of trade in 1974. The superimposition of the terms of trade shift on top of an existing trade imbalance caused the trade deficit to more than double in a single year.

The significant difference in the terms of trade experience of Poland, on the one hand, and Yugoslavia on the other, is largely explained by the fact that Poland was a net fuel exporter while Yugoslavia was a net fuel importer and had no major primary commodity export to serve the function of Polish coal. Yugoslavia was hurt by the fact that a very large share of its exports fell in the machinery and processed goods categories (usually well over half of Yugoslav exports), and the prices of these goods did not rise as fast as the prices of fuels and materials.

The deteriorating trade balance in both countries required immediate compensating movements in foreign indebtedness and foreign exchange reserves. In Yugoslavia, the 1974 deficit on current account was largely covered by drawing down of foreign exchange reserves and an increase in short term borrowings from abroad. In 1975 foreign exchange losses continued but the Yugoslavs were able to substitute long term borrowing for short term loans. Over the 1974-75 period, the total loss in reserves amounted to \$542 million. Moreover, by mid-1975 Yugoslavs switched to a restrictive domestic policy that led to a slightly smaller trade deficit in 1975.

As indicated in the Polish case study, Poland does not publish balance of payments statistics. Part of the deficit was covered by the invisibles, but Polish hard currency indebtedness rose from \$4.4 billion at the end of 1974 to \$7.1 billion at the end of 1975. A further response was the decision to moderate the rate of investment and to push exports in an attempt to achieve a positive trade balance by 1980.

## 2C. INVISIBLES ACCOUNT

One difference between Yugoslavia and Poland lies in the ability of Yugoslavia to compensate for extremely large trade deficits by earnings from invisibles, mainly tourism and worker remittances. The earnings from these two items amounted to about 63 percent of earnings from the export of merchandise during the 1971-75 period.

In the case of Poland, the major invisibles are railways transit operations, the merchant marine, and gifts from abroad. However, no data are available on the significance of these as earners of foreign exchange.

## 2D. GEOGRAPHICAL REORIENTATION

A possible way of coping with increased prices on world markets is to shift trade toward the CMEA market where prices are based on the average of prices in past years (thus, lagging behind world prices when these increase sharply). This mechanism is feasible for members of CMEA like Poland but not for Yugoslavia since it does not trade at intra-CMEA prices. In the case of Yugoslavia, trade with the centrally planned economies (primarily with members of CMEA) increased sharply from 1973 to 1974. In current prices, Yugoslav imports from this area rose sharply by 57 percent from \$1,117 million in 1973 to \$1,755 million in 1974. However, because total Yugoslav imports rose more rapidly, the share of CMEA imports in the total declined slightly. In the case of exports, a definite reorientation towards CMEA markets is suggested. Yugoslav exports to CPEs rose by 63 percent from \$970 million in 1973 to \$1,581 in 1974, and changed from 34 percent of total exports to over 40 percent. The conclusion one might draw from this is that the impact of the world inflation on geographical distribution was not as significant (since CPE share in imports did not change), as was the impact of stagnation in the West (which was the probable cause of Yugoslav efforts to increase their exports to the East when markets in the West could not absorb their goods).

In the case of Poland, the picture is rather complex since the evaluation of the geographic shifts depends on the choice of current or constant prices. As indicated in the case study, the share of Polish exports to socialist countries increased when evaluated in constant prices and decreased in terms of current prices. On the other hand, the share of imports from the West rose even when measured in constant prices. Thus, Polish containment of externally generated inflationary pressures did not include a shift in imports from the West to CMEA.

## 3. Conclusion

As argued in a previous paper,<sup>30</sup> international inflation may be expected to have three important potential effects:

- (1) a tendency to reverse the liberalizing and decentralizing economic reform measures by moving toward greater degrees of centralization and greater use of administrative measures in the attempt to contain the impact,

<sup>30</sup> Brown, Fallenbuchl, Licari, Neuberger, *op. cit.*

(2) a tendency to reduce the participation in the international division of labor and to try to return toward a policy of import substitution, and

(3) a tendency toward a shift in trading patterns away from the West and toward CMEA where prices have been held more stable by a pricing policy which sets CMEA prices as equal to the average of several past years' prices in world markets, thereby introducing significant lags into price increases (CMEA markets act as absorbers of price inflation).

In the case of Yugoslavia, the reaction to the 1973-75 world commodity inflation did not manifest the three postulated tendencies, with the exception of a small and probably temporary shift of exports toward CMEA. In the longer run, it seems reasonable to conclude that Yugoslavia will not abandon its decentralized economic system in response to external disturbances and will continue to maintain its trade relations with the West at their current high levels. The major new element in the future appears to be a shift in policy emphasis from export propulsion to import substitution.

In Poland the Plan for 1976-80 envisages a reduction in the import of steel and iron to 40 percent of the 1975 level as the result of the construction of the new gigantic steel mill "Katowice"; a change from a deficit to a surplus in grain trade; and an increase in the domestic content of the investment requirements for goods from 66 percent in 1975 to 74 percent in 1980.<sup>31</sup> This is clearly an increase in import substitution which can, at least partly, be attributed to the impact of world inflation.

As indicated above, there was a significant systemic impact of external disturbances but no major return to the orthodox centrally planned system. The postulated shift in geographic patterns certainly did not occur in the case of imports where it would be expected. The rise in the share of exports to CMEA, when measured in constant prices, was due to the stagnation in the West, rather than inflation.

This essay analyzes the origin, nature, and outcome of economic reform in the last decade in the planned economies of Eastern Europe. This group includes Albania, Bulgaria, Czechoslovakia, the German Democratic Republic (GDR), Hungary, Poland, and Romania. The study does not deal directly with reforms in the U.S.S.R. or Yugoslavia. The U.S.S.R., although a centrally planned economy, is outside the geographical scope set for this volume. Yugoslavia has a very different economic system combining market socialism, workers' self-management of enterprises, and private agriculture. However, the

\*Professor of Economics, The University of Michigan. This study is part of a research project at The University of Michigan Center for Russian and East European Studies funded by a grant from the Rockefeller Foundation. Source references in footnotes are to publications in the References section at the end of the paper.

U.S.S.R. and Yugoslavia are considered indirectly, in regard to their influence on reforms in the countries mentioned.

Because its focus is on the process of systemic change, the essay discusses major reform issues, forces, and measures common to most of the seven nations. It does not examine each country's experience separately, although important similarities and differences among countries are noted. Detailed accounts of reforms in particular nations may be found in the country papers in this volume and in earlier studies.<sup>1</sup>

Part I of the essay explains the pressures for, and the opposition to, changes in the economic system. Part II examines fundamental issues in designing reforms, and contrasts the main approaches adopted. Part III analyzes the subsequent retreat from economic reform. Part IV presents some general conclusions.

## I. THE REFORM MOVEMENT

The economic reform movement was an effort to change the traditional "command economy" model of comprehensive central planning and administrative control established in the U.S.S.R. in the 1930's and introduced into Eastern Europe after World War II. The reform movement can therefore best be understood by considering the nature and results of this traditional model, the pressures for change, and the sources of resistance to change.<sup>2</sup>

### A. *The Traditional Soviet Model*

The chief features of the traditional model include the following: (1) All significant means of production outside agriculture were nationalized. (2) In agriculture, the dominant pattern was collectivization, involving nominally cooperative ownership under close state control. (However, the collectivization drive was abandoned in Poland in 1956.)

(3) In the hierarchical system of economic organization, decision making was concentrated near the top. The different levels bargained about production assignments and the allocation of resources to meet them. Inter-enterprise relationships were determined "vertically" through the respective administrative hierarchies, rather than "horizontally" through the market. (4) Production and its disposition were planned in detail in physical units (as well as value terms). (5) To enforce these ambitious plans, the means of production were rationed—materials by administrative orders; labor by controls over the size (and sometimes the distribution) of wage expenditures; and capital by allocation of investment funds, construction materials, and machinery and equipment.

In turn, (6) prices were set administratively at high levels in the hierarchy and infrequently changed. Industrial wholesale prices were fixed on a cost-plus basis, with the aim of enabling most branches of industry to earn revenues sufficient to cover current (but not also capital) expenditures and show a small profit. Retail prices, often

<sup>1</sup> For example, see Feiwel 77 on Bulgaria, Keren 73 on the GDR, Friss 69 and Gadó 72 on Hungary, Zielinski 73 on Poland, Spigler 73 on Romania, and country chapters in Borstein 73 and Höhmann 75.

<sup>2</sup> Bornstein 73, pp. 2-8.

including a large element of excise taxes, were supposedly set near market-clearing levels, but they were frequently too low, as shown by persistent shortages. Agricultural procurement prices were low relative to retail prices for the same commodities and to prices for industrial inputs into agriculture, and various controls were needed to enforce procurement quotas. (7) Money was "passive" at least in the production sector: the flow of funds was adjusted by taxes, subsidies, and credit to implement the allocation of resources and goods previously made in physical terms. (8) Managerial and worker incentives stressed the fulfillment and overfulfillment of quantitative production targets.

Finally, (9) unrealistic exchange rates and a complex structure of taxes and subsidies separated domestic from foreign prices. Foreign trade was conducted by special export-import firms. Producing enterprises had no direct contacts with foreign customers or suppliers, and their interest in foreign trade was weak.

This model was originally applied in the U.S.S.R. in the 1930's to achieve rapid industrialization and military power in a large but relatively backward country with considerable supplies of unskilled labor and extensive natural resources. The aim was to secure rapid growth and drastic structural change, despite the economic and social costs, through the comprehensive mobilization of labor and capital under centralized administrative direction. However, it was much less relevant to the circumstances of the much smaller East European countries in the late 1940's—and even to those of the U.S.S.R. itself by the 1950's.

At the end of World War II, Czechoslovakia and the GDR were already industrialized by European standards. They had little surplus agricultural labor which could be shifted to industry, and their populations were accustomed to central European, not Soviet, living standards. Poland and Hungary were less industrialized, but still more advanced than the Balkan countries, which did have large underutilized agricultural labor forces. More important, all of these countries are much smaller than the U.S.S.R. and lack both its varied resource endowment and its potential internal market for large-scale production. Therefore, they are inherently much more dependent on foreign trade. Hence, the Soviet pattern of rapid development of heavy industry (for which some of the East European countries lack even the basic natural resources), at the expense of international specialization based on comparative advantage, did not fit the circumstances and needs of the East European countries.

The harmful consequences of the imposition of the traditional Soviet model became evident relatively soon and sharply in the more developed countries of the area, such as the GDR, Czechoslovakia, Poland, and Hungary, although later and less acutely in the less advanced countries like Romania and Bulgaria. Overcentralization of decision making, excessively detailed planning and rigid materials allocation procedures, the suppression of local initiative, unsound price structures, and overambitious targets led to visible waste and inefficiency. Shortages of both producer and consumer goods were chronic, while stocks of unwanted goods accumulated. Lacking adequate material inputs and incentives, the agricultural sector performed especially poorly. The low quality and technological lag of manufactured goods limited the possibilities for sale both within the Council

for Mutual Economic Assistance (CMEA) bloc and on the world market—making them “soft” goods in comparison with “hard” goods such as agricultural products, raw materials, and fuels.

Despite continuing high rates of investment, the accustomed high growth rates of national product and labor productivity began to decline by the late 1950's or early 1960's, depending upon the country. Throughout the area, capital productivity was falling as a result of investment programs which stressed the highly capital-intensive branches, devoted a large share to structures rather than machinery and equipment, failed to apply up-to-date technology, and dispersed investment over many projects, leading to long delays before new capacity was completed and production from it began.<sup>3</sup>

### *B. Pressures for Reform*<sup>4</sup>

Thus, by the early 1960's, a growing number of economists had begun to perceive and to express the need for economic reform, as part of a shift from a more centralized economic system in the “extensive” phase of economic development to a less centralized system in the “intensive” phase. This formulation was politically convenient because it enabled them to argue the need for change without as such condemning the traditional system, with which the Communist party leadership was so intimately involved. Instead, it was claimed that different conditions called for a different system of economic planning and management.

In the “extensive” phase, they asserted, the chief aims of “economic construction” had been to alter the structure of the economy drastically and rapidly—to industrialize, to urbanize, to adjust to changes in territory resulting from World War II, to develop backward regions, and to reshape the content and geographical orientation of foreign economic relations. The methods chosen for these tasks were socialization of the means of production, a sharp increase in the rate of investment, rapid expansion of the industrial labor force, and revision of the pre-socialist income distribution.

In contrast, in the “intensive” phase, reform advocates observed, the emphasis of economic policy was no longer on rapid structural change, as much as on smaller, marginal changes in the composition of output, technology, etc. With a slowdown in the rate of growth of the labor force, capital deepening rather than capital widening became important. Greater efficiency in the use of limited inputs was essential. Finally, in the consumer sector, for many goods a shift had occurred from a sellers' to a buyers' market, as a result of the rise in living standards and the availability of stocks.

Thus, they concluded, the economic system should be modified to deal with the new conditions of the “intensive” phase. More decisions should be made at lower levels in the hierarchy, on technical-economic rather than political grounds. However, to be sound, such decentralized decisions must be guided by more rational prices and by more appropriate performance indicators. Product mix and product characteristics should respond more closely to customer demand—for consumer goods as well as producer goods, and especially for exports. The

<sup>3</sup> Seidenstecher 75, p. 321.

<sup>4</sup> This analysis deals with pressures for economic reform. For an appraisal of pressures for political and cultural reforms, see Kusin 76.

coercion and ideological appeals used to mobilize resources in the extensive phase should yield to more emphasis on incentives to promote the efficient production of the correct output. Finally, they advocated a new approach to foreign trade, recognizing its importance as a source of innovation in technology and products, as a means of competition to discipline highly-concentrated domestic producers, and as a way to obtain economies of scale beyond the capacity of the internal market.

Discussion of the need for reform and of specific reform proposals was aided by political "de-Stalinization" after 1956, which permitted freer discussion of new ideas in the economic sphere and the inflow of information from abroad.<sup>5</sup> The latter brought both greater awareness of economic growth and living standards in Western Europe, and greater understanding of the operation of regulated market economies, in contrast to the "anarchic" capitalist economies depicted in orthodox Marxian writings. Thus, what was previously considered an issue of principle—for example, central formulation of detailed enterprise production plans—became a matter of technique, to be evaluated on its merits. As a result, it was possible to propose "mixed" economic models in which the central authorities could continue to control the main lines of economic development (including income distribution and foreign trade) through macroeconomic planning and monetary-fiscal measures, while permitting more enterprise autonomy in micro-economic decisions in response to market forces.

### *C. Resistance to Reform*

The political leadership was slow to recognize both the need for change and the form it should take. In the first place, it was reluctant to believe that the economic system itself, rather than the incompetence of individual officials, was responsible. In some cases, shortcomings in the statistical system failed to disclose the facts and causes of declining economic performance promptly and accurately. Reform was also opposed on ideological and philosophical grounds: Reliance on the market was deemed inconceivable in a socialist economy, because "socialism" was held to involve not only collective ownership of the (principal) means of production but also central planning of investment, output, prices, and distribution. Capital and land charges, production for profit, and emphasis on material incentives were condemned as incompatible with socialism. The official ideology of the "solidary society" denied any conflict between group interests. In contrast, reform proposals recognized the separate interests of firms, workers, and consumers, and recommended the market as the mechanism for reconciling them.

Reforms were also opposed by policymakers on somewhat more pragmatic grounds. (1) Some feared that the proposed systemic changes would mean loss of central (Party) control over the main directions of economic development. Whereas central planning could assure the priority development of those sectors deemed most important to the national welfare, decentralized decisionmaking by autonomous enterprises in response to market forces could lead to the diversion of resources from investment, military programs, and civilian collective consumption to supplying goods and services for

<sup>5</sup> See Korbonski 75 for a thorough analysis of the political aspects of economic reforms.

personal household consumption. (2) Because centrally planned economies typically operate under conditions of repressed inflation and administrative allocation (rather than price rationing) of many goods, more influence for market forces could bring rapid open inflation (as in Yugoslavia). This would in turn affect the distribution of income and popular attitudes toward the regime. (3) At the same time, unemployment could occur or increase, as enterprises laid off excess workers in response to a shift from output maximization to profit maximization, to more autonomy in the use of wage funds, or to the curtailment of budget subsidies. Also (4), reducing the artificial separation between the domestic economy and foreign trade, by linking domestic and foreign prices through more realistic exchange rates, could lead to higher domestic prices for imports, on the one hand, and make less attractive the production of exports needed to fulfill CMEA agreements, on the other. In short, some opposition to reform was based on an assessment of the risk and uncertainty attached to both the benefits and the costs of reform, including the problems involved in the transition from the old system to a new one.

Various interest groups resisted reforms. The Party apparatus and the ministerial bureaucracy believed they would lose power as enterprises obtained more freedom to make decisions in response to market forces—in place of the traditional system of joint supervision of enterprises by higher administrative agencies and by parallel Party organizations. In turn, some managers who were successful under the traditional system were not enthusiastic about reforms which called for them to become independent, cost-conscious entrepreneurs selling products in a competitive buyers' market—i.e., to become “businessmen” instead of production engineers.

For their part, workers were concerned about the impact on their real incomes of changes in wages and prices associated with reform. New incentive schemes might increase the money incomes of managerial and technical personnel and more-skilled workers relative to less-skilled workers. Retail prices might be increased, because the “rationalization” of the price system might reduce or eliminate subsidies for some consumer goods and services. Also, the curtailment of unprofitable production and greater freedom for managers over the enterprise wage fund and labor force might lead to at least frictional and perhaps even structural unemployment, despite a national macroeconomic policy of full employment.

Finally, economic reforms were opposed on the ground that liberalization in the economic sphere might spread, threatening the paramount role of the Communist party in national life. Freer discussion of alternatives in the economic sphere might lead in turn to demands for open discussion of cultural, social, and even political issues. Economic reforms imply some diffusion of power, first to enterprise management, but subsequently to the population through reliance on the market for guidance on the composition of at least part of the national output. It was feared that professionals in other fields might also seek greater autonomy in their activities, and that the population might be tempted to express its views on matters (such as living standards, housing policy, the length of the workweek) hitherto reserved to top policymakers.

## II. REFORM DESIGN

In view of these conflicting pressures, the designers of reform proposals had to face and resolve several important issues, including the choice between systemic and policy changes, the nature of the "decentralization" of decisionmaking to be sought, and the strategy for implementing reforms.

### *A. Systemic Versus Policy Changes*

It is important to distinguish between changes in economic policy and changes in the economic system, since they may represent alternative paths to improving the performance of the economy.<sup>6</sup>

Economic policy involves, for example, decisions on the rates of growth of major components of national product, such as consumption, investment, and military programs; the distribution of investment by sectors and branches of the economy and also by regions of the country; the school-leaving age, the retirement age, and the length of the work week; the relationship of changes in money wages and in retail prices; and the composition and geographical direction of foreign trade.

Thus, for instance, economic performance could—without systemic changes—be improved by economic policy decisions which allocated the same (or perhaps even a smaller) amount of investment differently among industries, changed the mix between capital-intensive and labor-intensive technologies, or raised labor force participation rates by altering the entry or retirement ages.

In contrast, modification of the economic system entails a redistribution of decision-making authority regarding various questions among the participants (central planning agencies, ministries, enterprises, workers, households). Corresponding changes in the flow of information used in decision making are commonly required. Also, to get the new decisionmaking structure to strive for the goals of the system designers, changes in performance indicators and incentives are often necessary.<sup>7</sup>

Hence, systemic changes seek to improve the economy's performance by such measures as transferring from ministries to firms authority and responsibility for decisions on the composition of output, the use of labor inputs, or the nature of new investment (at least below a specified ceiling amount). In turn, to provide firms the information needed for sensible decisions on these questions, prices may be revised to reflect more closely the relative scarcities of inputs and outputs. Finally, the dominant criterion for evaluating enterprise performance may be changed from output or sales to profit, and managerial incentives in the form of bonuses and promotions accordingly related to profit.

However, while it is possible to distinguish analytically between policy and systemic changes, they are often linked in practice. First, altering important features of the economic system is in fact a major economic policy decision—about the appropriate mechanisms for determining the bill of goods, allocating resources and distributing

<sup>6</sup> Chawluk, 74, pp. 98-100.

<sup>7</sup> The elements of decision making, information, and motivation are discussed in detail in Koopmans 71 and Neuberger 76, chs. 4-6.

income, and perhaps even about property rights. Second, changes in the economic system may be regarded as the best means to accomplish some policy decisions. For instance, to implement a decision to expand exports of manufactured goods to Western market economies, it may be necessary both to give producing enterprises the right to conduct directly (rather than through intermediary foreign-trade enterprises) at least some aspects of export sales, and also to assign realistic domestic prices to exports for use in calculating sales revenue, profits, and managerial bonuses.

Nonetheless, the distinction between policy and systemic changes proved a useful one for economic reform advocates, because they could claim to address themselves to improving the systemic mechanism to implement policy, without challenging the Party's exclusive right to determine policy.

### *B. Concepts of "Decentralization"*

Several different conceptions of "decentralization" of decision making appeared in the debates over economic reform.

The "administrative decentralization" approach involved partial devolution of authority over selected decisions from higher to lower tiers within the administrative hierarchy—for instance, from the ministry to the intermediate "association" level or even to the actual producing enterprise. Its intent was to "rationalize" the existing scheme of administering the economy, by transferring to lower levels some of the more detailed decisions regarding the composition of output, on the one hand, and production methods, on the other. The lower levels could make more sensible and more timely decisions on these aspects—though subject to constraints in the form of centrally set global output assignments and input authorizations. This shift would also reduce the burden of decision making at higher levels, freeing them to concentrate on their non-delegable responsibilities regarding investment, location, living standards, foreign economic policy, etc.

In contrast, the "economic decentralization" approach envisioned a greater role for domestic and foreign market forces—and concomitantly a smaller voice for central planning and administrative control—in determining the composition of output, the allocation of resources, and even the distribution of income. Enterprise activities would be co-ordinated through direct "horizontal" market links, rather than a "vertical" administrative command chain. Supply and demand, operating through more flexible domestic prices, which in turn would be related to world market prices, would guide decisions on outputs and inputs. Profit—the "synthetic" indicator simultaneously encompassing all aspects of enterprise activity—could then become the appropriate measure of a firm's contribution to the economy, and the basis for rewarding its personnel.

In short, the "economic decentralization" approach contemplated a move toward a socialist regulated market economy. The state authorities would still control the "main directions and proportions" of the economy through macroeconomic policy decisions and instruments (taxes, subsidies, credit) to promote growth and maintain stability of the price level and employment. They would also provide collective consumption and intervene to deal with externalities. But

within this regulatory framework, “the market,” not “the plan,” would guide the microeconomic decisions of enterprises about what to produce and how to produce it.

These two concepts of “decentralization” concern what powers should be transferred to firms from central planning agencies and ministries. A third approach to decentralization involved devolution of authority *within* firms—through a shift from “one-man management” (according to the Soviet principle of *edinonachalie*) by a state-appointed manager to genuine “mass participation” in decision making by workers along the lines of the Yugoslav model. Some reform advocates regarded self-management as the logical completion of the process of decentralization.

### C. Implementation Strategy

Should reform measures—once selected—be introduced in phases, or all together? In selected units on an experimental basis, or across the entire economy? Subject to continuous adjustment, or with a promise of stability? Each of these issues will be discussed briefly.

#### 1. PHASED VERSUS SIMULTANEOUS INTRODUCTION

Should different reform measures—for example, concerning performance indicators, authority regarding the output mix, foreign trade rights, and so forth—all be implemented at the same time, or should they be introduced separately in a particular sequence over several years?

Supporters of the phased approach pointed out that some reforms, such as a change from gross output to sales as an enterprise performance indicator, could be adopted immediately, while other measures, particularly price reforms, would take a long time (years rather than months) to prepare. Also, a phased approach was claimed to be less disruptive, permitting enterprises to adjust to one new responsibility before undertaking another.

In contrast, opponents of the phased approach argued that meaningful and successful reform required the simultaneous introduction of an integrated package of mutually supporting measures affecting planning methods, performance indicators, incentives, and prices. Otherwise, a change in only one or some of these aspects of the economic system could yield little improvement and could even prove counterproductive. For instance, if firms gained more power to determine the composition of output without facing new prices more nearly reflecting scarcities, decentralized decision making by individual enterprises might well produce an even less suitable assortment than that generated by the admittedly imperfect decisions of central planning agencies—which at least had a broad economy-wide perspective that partially compensated for the deficiencies of misleading prices.

#### 2. EXPERIMENTATION VERSUS COMMITMENT

Should reform measures—whether phased or simultaneous—be “tested” by applying them for a trial period only to a selected group of enterprises, or should they be adopted uniformly across the economy (perhaps with the exception of cooperative agriculture)?

The first school held that it was logical and "scientific" to determine the feasibility of reform measures by trying them first in a "pilot" group of ministries and enterprises. In the light of the results obtained, the Party could then decide whether to modify some of the reform measures and whether to extend them to other units and eventually the entire economy.

Critics questioned what could be learned from such experiments. First, they would yield atypically favorable results if—as usually contemplated—the "pilot" group comprised not a representative sample of enterprises but rather a set of the most efficient enterprises, enjoying modern equipment, the best management, and priority in the allocation of materials and machinery. Second, how could any selected "pilot" group of firms truly operate on the new system if the rest of the economy—including their suppliers and customers, and the prices of inputs and outputs—were not also "reformed"?<sup>8</sup> Finally, how long should an experiment run? Presumably, it should be long enough to show convincingly the results of the new arrangements. But scheduling experiments of several years' duration could easily constitute a delaying tactic intended to postpone further implementation of the reform package.

### 3. ADJUSTMENTS VERSUS STABILITY

Should reform measures be continuously evaluated and modified as soon and as often as experience showed any changes to be necessary? This approach has the advantage of flexibility—conceding the possibility of error, and making corrections promptly as required.

Or should reform measures be "stable", so economic agents can have time to learn how to perform their new roles and to accept them? Frequent changes in "ground rules" can weaken confidence in, and commitment to, reforms. For example, this would occur if enterprise managers found that, after they had "mobilized internal reserves" in order to increase profits, the central authorities raised profits taxes, preventing managers from using the additional funds for bonuses as they had expected.

#### *D. Reform Models*

This essay does not present a detailed comparison of the original reform "blueprints" of the individual countries in regard to each of the various possible measures. First, such comparisons are available in several earlier studies.<sup>9</sup> Second, and more important, these blueprints soon became outdated, as many important features were not implemented fully or at all.

Instead, in the light of the issues identified in the preceding sections, we may briefly characterize the various national reform blueprints by grouping them into two broad categories: "partial" or "minor" vs. "comprehensive" or "major" reforms. This classification is analytically useful and appropriate for the purpose of this essay, but it unavoidably disregards some interesting, and in some respects

<sup>8</sup> The point is neatly illustrated by a popular Hungarian example about a hypothetical proposed reform of the traffic system in Great Britain from driving on the left to driving on the right. In this case, the "experimentalists" advocate testing the merits of the new system by at first switching to the right only buses, while all other vehicles continue on the left.

<sup>9</sup> For example, Kaser 70; Bornstein 71, pp. 262-63; and Pryor 73, ch. VII.

substantial, differences among nations in each group—as can be appreciated by consulting the country studies in this volume.

As in the U.S.S.R., a “partial” reform approach was chosen by Albania, Bulgaria, the GDR, Poland, and Romania. It stressed “administrative” decentralization, though in many respects only to an intermediate “association” level between the ministry and the enterprise. It included phased introduction of reform measures, selective experiments, and an inclination toward early revision. The detail of enterprise plan targets was reduced, managers gained more control over the use of the wage fund, and some decentralized investment by firms was promised. Sales and profit became more important performance indicators, with bonuses linked to them. Selected producing units received the right to engage directly in foreign trade, within their global plan assignments. Producer (wholesale) prices were revised to reflect costs more closely, but were not expected to balance supply and demand—a task still assigned to administrative allocation, though now to be performed in some cases at a lower hierarchical levels.

In contrast, the more “comprehensive” reform blueprints in Czechoslovakia and Hungary accepted a considerable degree of “economic” decentralization, and the Czech (but not the Hungarian) reform also called for workers’ self-management of enterprises. The various reform measures were to be introduced simultaneously in Hungary (though phased in Czechoslovakia), and applied to all firms. “Parameters” (or “regulators”) such as taxes and subsidies were to be left unchanged for at least several years, to provide a stable environment for enterprise decisions on production and investment. Reform included abolition of obligatory targets for enterprises, distribution of supplies by the market mechanism, designation of profit alone as the key performance indicator, and direct participation by firms in foreign trade. In turn, to provide appropriate signals to guide enterprises’ exercise of their new rights, reform of the price system involved not only closer correspondence of prices with costs but also an effort to make prices more flexible and more reflective of scarcity, through progressive decontrol of centrally fixed prices.

### III. RETREAT FROM REFORM

Despite the long period (usually two–four years) devoted to working out national economic reform blueprints, none of them was fully implemented. In some cases, key changes were never put into effect. In others, reform measures were introduced but then formally revoked, wholly or partly. Finally, some aspects of reforms survived in name only, as they were subsequently effectively abridged by offsetting recentralizing actions.

The first section below examines experience in implementing the chief reform measures. The second section then analyzes the major factors responsible for the retreat from economic reform.

#### *A. Implementation Experience*

Although the countries in the area differed in the way and extent to which reform blueprints were implemented, some common patterns can be identified in regard to the principal reform measures. These include (1) administrative reorganization, (2) output plan assign-

ments, (3) allocation of supplies of material inputs, (4) use of labor, (5) investment, (6) price formation, (7) performance indicators, (8) incentives, (9) foreign trade, (10) workers' participation in decision making, (11) agriculture, and (12) the scope of the private enterprise sector. Experience regarding each aspect will be discussed briefly.

#### 1. ADMINISTRATIVE REORGANIZATION

National reform blueprints based on "administrative" decentralization were reluctant to devolve much authority down to the enterprise and thus the market. Instead, they chose a compromise solution under which certain powers were to be transferred from the ministry, not to the enterprise, but only to an intermediate hierarchical level. The "main administrations" within ministries were renamed "associations" and changed from purely administrative organs, financed by budget grants, to "business organizations" on "economic accountability" status. This status, following the Soviet concept of *khozraschet*, involves separate financial accounts, meeting expenses from sales revenue, partial financing from repayable bank credits, and profit as a performance indicator and basis for bonuses. The association was thus a hybrid: a combined administrative unit and business entity—receiving targets for outputs, inputs, and investment from the ministry, and distributing disaggregated plan assignments to its component enterprises, in pursuit of sales and profit.

Thus, in the GDR the VVB were formed in 1958 from the main administrations, and in 1964 were put on economic accountability status, with performance indicators and incentives similar to those of enterprises. In 1968, some enterprises were further integrated vertically into "combines." In Bulgaria, the association was made the basic business unit: all plan targets, input allocations, budget grants, and credits were channeled to it, and it was responsible for plan fulfillment by its subordinate enterprises. In Poland, the consolidation movement went farther with the creation in 1973 of "big economic organizations" (WOG) combining large multiplant enterprises, vertical complexes, and associations.

(There was no similar reorganization in Hungary, where industry was already highly concentrated after a reorganization in 1963 which preceded economic reform. About 800 state industrial enterprises—half with over 5,000 workers each—produce over 90 percent of total industrial output. This concentration permits ministries to exercise effective control over enterprises directly, without an intermediate association level.)

However, even the promised limited devolution of authority from the ministry to the association was not realized in practice, as the experience of the Romanian "centrals" vividly illustrates.<sup>10</sup> After a short and small experiment with 10 of these associations, a total of 200 were established in 1969, involving both horizontal and vertical integration. In some cases the central was set up as a single large enterprise combining a number of previously independent firms whose identity was lost. In other cases the latter remained as distinct divisions of the central. Finally, in some instances both the central and the component enterprises had separate economic accountability

<sup>10</sup> Spigler 73, chs. 3-4, and Granick 75, ch. 4.

status and individual managements. Within the framework of plan assignments from the ministry, the new centrals were supposed to draw up plans for their member plants; allocate materials and investment funds; sell the output, with the right to direct contacts in foreign trade; and redistribute profits among component units. It soon became clear that ministries would not permit centrals to exercise these rights. From the outset ministries intervened in the day-to-day operations of the centrals and in their instructions to member enterprises, which had to report (formally and informally) to the ministries. The only real autonomy of the centrals proved to be in scheduling production among their plants. In 1972, most of the rights of the centrals were formally rescinded, and in 1974 their number was reduced to 102, to facilitate close control by the ministries.

## 2. OUTPUT PLANS

The "comprehensive" approach of Hungary (and Czechoslovakia) abolished centrally set output targets for enterprises. They were instead to determine the level and composition of their output for themselves, in pursuit of profit and in the light of customers' demands, prices, and costs.

In the "partial" reforms of other countries, ministries continued to set global output targets for producers. But in most cases, the concept of output was changed from gross value of output to actual sales of finished products to customers. In addition, the "partial" reforms usually called for less ministerial specification of the "assortment" or product-mix within the assigned global total.

However, the actual increase in enterprise autonomy was much less than promised. First, as explained in the preceding subsection, in many cases the association still worked out detailed output plans for enterprises. Second, central planning agencies and ministries assigned associations and enterprises binding targets for various high-priority consumer, producer, investment, or export goods which the higher levels knew the producing units would find it unprofitable to make and sell at the prevailing distorted, non-scarcity prices. Finally, producers received "informal," but irresistible, guidance in "direct discussions" between state officials and enterprise executives about the latter's responsibility "in the public interest" to produce specified quantities of designated goods despite the adverse effects on their sales revenue, profits, and bonus funds.<sup>11</sup>

## 3. DISTRIBUTION OF MATERIAL INPUTS

Allocation of raw, semifinished, and finished materials; fuels; and machinery and equipment and parts for them has traditionally been regarded as the fundamental "lever" of central control over the economy—determining what shall be produced, where, how, and for whom. Moreover, with producer goods prices based chiefly on cost and neglecting demand, administrative rationing logically supplants price rationing of scarce supplies. As a result, in centrally planned economies material inputs have long been distributed through a two-step process, involving (a) aggregate "balances" to equate total

<sup>11</sup> Cf. J. Fallenbuchl's article on Poland in this volume, and Tardos 75a and Bauer 76 on Hungarian experience.

sources and total uses for thousands of items, and (b) quantitative quotas for each consuming firm.

Yet in practice it has proved extremely difficult and burdensome for central agencies and ministries, remote from both suppliers and customers, to plan accurately the flows of thousands of items among thousands of firms—and to change these allocations promptly and correctly in response to new output assignments or to under- or over-fulfillments of plans.

Hence, the “administrative” decentralization approach to economic reform was sympathetic to proposals to preserve the principle of administrative, rather than price, allocation of materials, but to transfer to lower hierarchical levels the responsibility for many less important and/or more detailed commodity balances. However, although some reform blueprints accepted this idea, it was either not implemented or did not survive long, as the experience of Romania and the GDR, respectively, illustrate.

In Romania, the reform directives provided for a reduction in central planning of supplies and the transfer, from ministries to associations and enterprises, of authority to distribute output. But these decentralizing measures were never carried out. Instead, central control of supply was tightened, and a new ministerial-level agency was established to perform it.<sup>12</sup>

In contrast, in the GDR devolution actually occurred but was subsequently revoked. In 1973, the last year before the introduction of the “New Economic System” (NES), out of 5,192 commodity balances, 1,188 were prepared at the highest hierarchical level (by the State Planning Commission and the National Economic Council) and only 605 by associations and enterprises. In 1967, at the height of the NES, out of 6,045 balances, 138 were drawn up at the top and 5,728 by associations and enterprises. However, in response to supply problems arising from taut planning, beginning in 1972 recentralization occurred in two forms. First, formal authority for compiling many balances (the exact number is unclear) was shifted back up to ministries and the State Planning Commission. Second, the latter were given the responsibility to “confirm” balances initially prepared by lower levels.<sup>13</sup>

As part of “economic” decentralization in Hungary, for all but a very few products administrative allocation was to be eliminated and firms freed to distribute output on the basis of contracts negotiated between suppliers and customers in a market framework. Thus the National Board for Materials and Prices (NBMP) was to be concerned overwhelmingly with adjusting prices rather than allocating materials. But in practice much more central control over supply was exercised. At first, it was accomplished chiefly through informal “guidance” to enterprises by planning agencies and ministries expressing their concern about “equilibrium of the market.” Subsequently, central supervision was formalized by the creation of an Intersectoral Committee for Price Setting and Product Marketing, chaired by the head of the NBMP. The new agency is explicitly authorized to abridge enterprise autonomy by regulating output, inventories, and distribution of both domestic production and exports and imports.<sup>14</sup>

## 4. LABOR AND WAGES

With minor exceptions,<sup>15</sup> East European economies do not allocate labor administratively but instead rely upon differential wages in a labor market to place workers (in the light of their training) in particular occupations, branches of industry, firms, and geographical locations. These labor markets are usually "tight" because ambitious development plans maintain a high level of aggregate demand and because enterprise managers respond to taut plans by trying to acquire "excess reserves" of labor. In these conditions, the central authorities are typically concerned about labor shortages; a tendency for actual earnings to rise faster than official wage scales are raised; and the possibility of wider differentiation of income, by occupation and employing firm, than is considered tolerable in an "egalitarian" socialist society. To deal with these problems, the authorities set wage rates and then attempt to control firms' use of labor by regulating the wage bill rather than the number and kind of workers as such.

In no country of the area did the economic reform blueprint call for decentralization of authority to fix wage rates. Rather, in order to carry out a comprehensive and consistent revision of wage schedules, the power to set wage rates was often further centralized by transferring it from branch ministries to an economy-wide commission. In most of the countries, these revisions had three aims: (a) changing work norms to increase the share of basic wages (and reduce the share of bonuses) in total earnings; (b) altering (usually narrowing but sometimes widening) wage differentials by occupation, skill, and industrial branch; and (c) a limited shift from piece rates to time rates.

In contrast, economic reform did bring some loosening of control over the enterprise's wage bill and use of labor.<sup>16</sup> Previously, the ministry usually specified both the total wage bill and the average wage—which, along with centrally set wage rates, severely constrained the enterprise's freedom to determine the total number of workers and their composition.

In the "partial" reforms, the ministry still planned the wage bill—but no longer also the average wage—of the association or the enterprise. In some countries, for instance the GDR, the wage bill was stated as an absolute sum, on the basis of planned output or sales. On the other hand, under the scheme introduced in Poland in 1973, the wage bill is not specified directly but is determined indirectly as a percentage of value added. For every percentage point of increase in value added over the previous year, the enterprise is entitled to increase its wage bill by a fraction (usually 0.6–0.7) of one percent. Thus, the ministry designates not the wage bill itself but rather (a) the performance indicator determining it, and (b) the "normative" connecting the two.

In contrast, in the more "comprehensive" Czech and Hungarian reforms, the central authorities were no longer to determine enterprise wage bills but were instead to try to control labor use by regulating only the average wage paid by the enterprise. Thus, in the light of the output program it chose, the enterprise was to decide

<sup>15</sup> For example, new university graduates in certain fields, such as medicine or primary education, whose initial placement is in rural areas.

<sup>16</sup> See Adam 76 for detailed comparisons of particular countries.

its labor inputs—subject to constraints in the form of (a) centrally set wage rates and (b) an enterprise income tax levied in relation to the increase in the average wage.

For example, the abortive Czech reform at first included a two-part stabilization tax. One part was aimed at regulating wages and provided that if average wages increased compared to the previous year, the enterprise was liable for a tax equal to 30 per cent of the additional wage payments. The second part sought to regulate employment, stipulating that if the number of employees rose, the enterprise owed in tax a sum equal to the wages paid to the new employees. However, this control of enterprise wage payments and employment through taxation was soon reinforced by a scheme of coefficients linking permitted increases in average wages to increases in labor productivity. Furthermore, these coefficients were differentiated by branches and even individual enterprises. Finally, in 1970 ministries returned to specifying enterprise wage bills on the basis of planned sales.

In Hungary, an increase in the average wage of the enterprise depended on the increase in gross income (wages plus profit) per employee. For every percentage point increase in gross income per employee, the average wage could be increased by 0.3 per cent, provided that the enterprise could pay a tax (out of its bonus fund) equal to 50 per cent of increased wage costs. These coefficients were uniform for all firms in Hungary, in contrast to the differentiation of coefficients by branches and enterprises in Czechoslovakia. However, the Hungarian authorities soon found that this average wage regulation scheme led to intra- and inter-enterprise wage differences which caused serious dissatisfaction among less skilled production workers. As a result, in 1974 a new wage schedule was adopted centrally for 108 “key trades,” to be applied across the economy. It was intended to narrow the range between lower and upper limits in the various occupations from the prevailing 60–80 per cent to about 30 per cent. And in 1976 the central authorities resumed the regulation of enterprise wage bills as well as average wage levels.

Thus, even in the most liberal reform, the enterprise does not have the freedom to hire the workers it considers necessary, and pay them what it believes they are worth, in the light of their contributions to sales and profit.

##### 5. INVESTMENT

Reformers advocated some decentralization of decision making regarding investment, as well as related changes in methods of financing it. They hoped thereby to increase the “effectiveness” of investment by altering its distribution among products and firms, and among types (buildings, equipment, inventories); by lowering building costs; by finishing investment projects faster and reducing the backlog of uncompleted investment in process; and by thus more quickly introducing into production “embodied” technological progress involving investment in new methods and products.<sup>17</sup>

Reform proposals called for devolving some authority for selecting, designing, and carrying out investment projects from central planning agencies and ministries to associations and enterprises. The higher

<sup>17</sup> On investment problems, see Seidenstecher 75.

levels in the administrative hierarchy would still retain responsibility for big, non-recurring projects of national significance, but now permit the actual producing units to decide investments involving replacement, expansion, and modernization.

These enterprise-determined investments would be financed from three sources: depreciation allowances, profits, and bank credit. Total depreciation allowances should be increased, by raising depreciation rates and by revaluing upward the capital stock to which the higher rates were applied. Of the total amount of depreciation allowances, enterprises would retain a larger share (and transfer to ministries a smaller share) than before. Next, reform blueprints typically included schemes for the distribution of profit among taxes, bonus funds, reserve funds, and funds destined for "productive" and "non-productive" (e.g., housing) investment by the firm. Finally, enterprises would borrow at interest from the banking system, not only for working capital as previously, but also for fixed investment in buildings and equipment.

Most countries in the area did not implement to any significant degree changes in either the locus of investment decision making or the methods of finance. The central authorities feared that enterprises' interest in investing—to expand output, sales, profits, and wage funds—would increase the existing strain on the capacity of construction firms and on supplies of building materials and productive equipment. In addition, they doubted whether the prevailing non-scarcity prices of outputs and material inputs would guide decentralized investment decisions in the correct directions.

Therefore, the retained profits available for decentralized investment were strictly limited, often by profits taxes differentiated by firm. Second, the amount and distribution of bank credit for enterprise investments were closely controlled by direct quantitative rationing, rather than by altering interest rates. Since most decentralized investments could not be financed entirely from retained profits but needed also bank loans (and even budget grants as well), the availability of the latter conditioned the use of the former. Finally, through their control of the material supply system, the central authorities prevented enterprises from translating the nominal purchasing power of funds from retained profits and depreciation allowances into actual command over construction services, materials, and equipment.

Hungary at first did permit firms to undertake decentralized investments from profits and bank credits, but the resulting spurt of enterprise spending on investment caused severe shortages of construction materials and serious inflationary pressure, and central control—particularly through the banking system—was soon reasserted. Thus, as Portes' contribution to this volume notes, Hungarian claims that enterprises decide two-thirds of total investment are misleading, since these "enterprise decisions" are in fact guided formally and informally by the central authorities.

## 6. PRICES

Reform blueprints included two rather different types of changes in the price system: (a) extensive revisions of centrally-set (nonagricultural) prices, though essentially within the traditional cost-plus

framework; and (b) partial decontrol of prices in an effort to increase price flexibility in response to market forces. The first approach was carried out, though sometimes with great delay, in all of the countries. The second was proposed in Hungary, Czechoslovakia, and Bulgaria but implemented (partially) only in Hungary.

The revisions of producer prices involved changes both in the coverage of cost and in the basis for the profit markup added to cost to obtain the price. Most countries revalued fixed assets, to get more realistic depreciation charges. With the exception of Romania, they also introduced some kind of capital charge—either as an element of cost or in the form of a special tax to be paid out of the profit markup above cost. However, the several countries differed in regard to (a) the size of the capital charge, (b) whether it was differentiated by branches and enterprises, (c) whether it was calculated on the depreciated or the undepreciated value of assets, and (d) whether it applied to inventories as well as fixed capital (and if to both, whether at the same rate). Finally, in Hungary (as in the U.S.S.R.) rental payments for some natural resources were adopted.

Preceding the reforms, there had been a long debate in most countries about whether the profit markup should be calculated as a percentage of (a) the wage fund, (b) production cost (as previously), or (c) capital. In addition to these "single-channel" methods, a compromise "two-channel" method related part of the profit markup to the wage fund and another part to capital. Following the Soviet example,<sup>18</sup> the East European countries chose the variant relating the profit markup to capital—a scheme sometimes called "prices of production" following the use of this term by Marx in *Capital*, Vol. III—although they did not establish a single, uniform rate of profit in relation to assets for every branch of industry.

However, although profitability was now calculated in relation to assets by branch, this principle could not be carried down to separate products, because it was impossible to determine the amount of assets involved in the production of each item. Hence, the prices of individual products were still formed by adding a profit markup to cost, though with the aim that the sum of profits so derived should yield the desired branch profitability rate in regard to capital. Profitability rates in relation to cost continued to vary widely by product, making some items in the firm's "assortment" much more "advantageous" to produce than others. Also, since price was related to the branch average cost of production, profitability of the same item varied widely by firm, from high profits for low-cost producers to low profits or losses for high-cost firms.

Moreover, because they were set essentially from the supply side, largely neglecting demand (with some exceptions, such as substitute fuels), these prices did not reflect relative scarcities and thus permit the elimination of administrative allocation of materials and equipment. Finally, the widespread revision of producer prices was carried out with little or no alteration in final retail prices to consumers—since changes in the latter, if not offset by changes in wages and transfer payments, would have caused great popular dissatisfaction, as Polish experience has shown.

<sup>18</sup> See Bornstein 76, pp. 21-25.

Thus, little progress was made in eliminating subsidies, on the one hand, and widely varying tax rates on the other. The force of prices in guiding production was therefore limited: if the enterprise could not cover planned costs from planned sales revenue—with both assigned to it by its hierarchical superior—the enterprise had to be assured a subsidy to cover the difference. Widespread use of taxes and subsidies continued to separate both the levels and the structures of producer prices and consumer prices. Hence, the influence of final consumer demand upon production remained weak.

The GDR reform tried also to introduce “dynamic” prices (analogous to “stepped” prices in the U.S.S.R.). As costs fell and profitability rose, the price of a product was to be reduced. At first, the responsibility for initiating these price cuts was delegated to the VVB (association) level. But experience showed that the VVB had little interest in pursuing price cuts which reduced profits, and responsibility for changes was recentralized three years later.

To increase the flexibility of the price mechanism, reformers in some countries advocated a multi-category scheme of price control. (a) “Fixed” prices would be established centrally at a specific level. (b) Some prices would be set centrally only as “maximum” prices, with sellers allowed to charge less. (c) On other items, the central authorities would fix ceiling and floor prices, but permit sellers to adjust prices between these “limits.” Finally, (d) “free” prices would be determined by direct negotiations between seller and buyer. The long-term objective was to decontrol prices gradually by shifting them from more tightly to less tightly regulated categories.

In Bulgaria, a three-tier scheme (of fixed, limit, and free prices) was officially espoused during the reform debate, but the reform guidelines actually approved in 1968 did not include this approach. In Czechoslovakia, the multi-category principle was formally adopted, but not implemented before the intervention by Warsaw Pact forces in 1968 halted the reform movement.

In Hungary, a four-category scheme was cautiously implemented in 1968.<sup>19</sup> The bulk of raw materials were put in the “fixed” and “maximum” categories. Over three-fourths of inter-producer sales of finished goods were formally placed in the “free” category, but control of these prices was effectively exercised through the close regulation of the prices of the raw and semi-finished materials constituting inputs into finished goods, and through supervision of wage expenditures at all levels of production. Agricultural procurement prices remained under close control also. Because a relatively stable retail price level is a cornerstone of Hungarian economic policy, all key items of mass consumption were assigned to the tighter control categories, and only about one-fourth of household consumption expenditures (chiefly fashion items and imported goods) were put in the “free” price category.

At the time of the 1968 reform, its designers hoped (a) that the share of the “limit” and “free” categories in total sales would steadily increase; (b) that prices in the “maximum” and “limit” categories would often be below the ceiling; and (c) that in the “free” category supply and demand forces would lead to price decreases as well as increases. However, after 1968 none of these hopes was realized to a

<sup>19</sup> Bornstein 77 and Hare 76.

significant degree, because of inflationary pressures of domestic and foreign origin. Whereas in 1968 it was expected that the share of the "free" category in consumer expenditures would rise from about 23 percent in 1968 to about 50 percent in 1975, the actual 1975 figure has been estimated at only 35-38 percent. Moreover, various forms of official guidance of "free" prices were introduced, including rules for cost calculation and guidelines for distinguishing "fair" from "unfair" levels of profit above costs so calculated. Hence, little devolution of control over price formation has actually occurred in Hungary.

#### 7. PERFORMANCE INDICATORS

In centrally planned economies, enterprises have multiple performance indicators, which may be grouped into three categories according to their scope or breadth. (a) The narrowest indicators are those referring to an individual productive activity of a firm, such as the output of a particular item, or the introduction of a specific new production process. (b) Somewhat broader are "partial synthetic" indicators expressed in value terms and covering one entire aspect of enterprise operations, like total output, total sales, or total costs. (c) The broadest indicator of all is profit, the residual which reflects all decisions regarding outputs and inputs (and, over a longer time horizon, investment as well). The thrust of reform proposals was to reduce the number of indicators by placing more emphasis on broader indicators.

First, its hierarchical superior should no longer judge enterprise performance by the fulfillment of assignments for such narrow facets of activity as the extent of subcontracting, the growth of labor productivity, the level of inventories, or the introduction of a new machine.

Second, the traditionally dominant indicator of gross value of output should be replaced by sales or value added, because they more nearly represent what society wants from the firm. Gross value of output includes production for the enterprise's own use, such as building repairs and manufacture of replacement parts for machinery; the change (positive if an increase, negative if a decrease) in unfinished production; and the change (positive or negative) in inventories of finished goods. In contrast, sales refers to the dispatch of finished goods to customers. Finally, some reformers considered the most appropriate indicator to be value added (or net output)—usually calculated as the difference between sales and the cost of materials, interest charges, and other payments to entities outside the firm—because it showed the enterprise's contribution to the national income.

Although profit appeared the ideal "comprehensive" performance indicator to some reformers, most recognized that socialist firms could not become true "profit centers" in the sense described in Western management literature. Because centrally set prices did not (even after "price reforms") reflect relative scarcities, the central authorities would not let enterprises single-mindedly pursue profit by adjusting outputs and inputs in the light of those prices. Rather, at most, firms could strive for a kind of "constrained" profit maximization, subject to (maximum or minimum) restrictions which superior agencies imposed on enterprise output, inputs, and investment. Hence, profit could be made a more important performance indicator than previously, but not the sole indicator to the exclusion of some measure of output—gross, sold, or net.

Thus, gross output remained the chief success criterion in Romania, sales was adopted in the GDR, and value added chosen in Poland. In Hungary, with the abolition of central assignment of obligatory plan targets for enterprises, profit nominally became the only performance indicator. But in practice, as explained above, formal and informal supervision of enterprise output level and composition, input use and wages, and prices effectively limits how enterprises can earn profit, as well as its disposition once earned.

#### 8. INCENTIVES

It is the task of the incentive structure to motivate enterprise personnel to strive for good performance in regard to the indicators chosen and the quantitative targets for each indicator in a particular production period. Communist societies have long used both "moral" and "material" incentives for this purpose. "Moral" incentives can appeal to an individual's genuine wish to do whatever is best for society, as this is defined by the state authorities, or to the less unselfish desire for a reward in the form of public recognition and social prestige. In contrast, "material" incentives include both more money income, to be spent on the market (or saved), and material rewards available through non-market channels, such as preference in the allocation of housing or access to special stores not open to the general public. Although appeals to moral incentives continue in the educational system and the media, the East European countries (like the U.S.S.R.) in practice rely overwhelmingly on material incentives to motivate workers and managers—in contrast to the People's Republic of China, where moral incentives (and coercion) have a much greater role.

The actions of individual workers seldom can affect the overall performance of the firm. Therefore, East European incentive systems for workers typically award bonuses for successful or exceptional execution of particular tasks at the workplace, such as economizing on the use of scarce materials or meeting new quality standards, or for adopted suggestions on "rationalizing" production methods. These bonuses traditionally have come from a special portion of the enterprise wage fund, and this practice was retained in most reform proposals, although in Romania bonus payments to workers come out of profits.

The reforms were more concerned with bonuses for managerial personnel, whose individual decisions directly and strongly affect enterprise results regarding output, cost, and profit. Managerial bonus schemes have several elements: (a) the performance indicators whose targets must be fulfilled to qualify for bonuses, (b) a schedule of coefficients stating what results for each indicator will earn what amount of money for the bonus fund, (c) the source of money for the bonus fund, and (d) how the bonus fund is distributed among eligible employees.<sup>20</sup>

The most striking feature of East European bonus schemes is their complexity in the first and second respects. Because enterprises typically have not one but many performance indicators (for reasons explained above), bonuses must in some way reward good results

<sup>20</sup> See Granick 75 for a detailed discussion of managerial bonus systems in Romania, the GDR, and Hungary.

for each indicator. This may be accomplished directly by establishing separate bonuses for each performance indicator, with the respective coefficients or amounts reflecting the relative importance of the different indicators (e.g., sales vs. profit) in the eyes of the firm's hierarchical superior. Or it may be done indirectly through the use of side-conditions, by making the bonus for one indicator contingent upon fulfillment of the plan for another indicator which does not nominally offer a bonus. For example, a bonus due for sales performance may be paid only if the firm has also fulfilled its export assignments, for which no explicit bonus is provided.

The source of funds for managerial bonuses is usually a portion of retained profit, rather than the wage fund as in the case of bonuses for workers. In the GDR and Romania, however, managers may also receive bonuses from special ministerial funds. Such bonuses are paid not according to explicit formulas related to plan fulfillment, but rather on the basis of a more subjective evaluation by the ministry of managerial performance and thus (like promotion) can reward managers who respond properly to "informal" guidance from above.

Reformers advocated establishing incentive structures which were uniform across enterprises (at least within a particular branch of industry) and stable for a number of years. The first feature would bring the management of leading firms higher bonuses than their counterparts in less successful enterprises. The second feature would encourage managers to reveal "reserves" by reducing their fear that when sales or profit rose the bonus coefficients would be changed to prevent managers from reaping the fruits of their efforts.

However, in practice in most countries bonus schemes were not made uniform but instead were tailored by the ministry to its view of the particular circumstances of the individual enterprise or association, with the aim of preventing bonuses in stronger units from becoming too large relative to those in weaker units. In addition, despite assurances that "normatives" for payments to bonus funds would remain unaltered, they were changed frequently and even retroactively. As Fallenbuchl's paper on Poland in this volume points out, managers are not likely to have confidence in a system in which the "rules of the game" are changed not only during, but even after, the game. Finally, in Hungary, where a common formula for determining the size of the bonus fund was applied to all enterprises, the maximum possible size of managerial bonuses was reduced sharply after workers expressed their resentment at the effect of bonuses in widening income differentials between managerial personnel and production workers.

## 9. FOREIGN TRADE

In the traditional pre-reform system, foreign exchange rates were usually quite arbitrary. Producing firms sold exports to, and bought imports from, special foreign trade enterprises at domestic prices completely divorced from the prices at which the foreign trade enterprises dealt with their customers and suppliers abroad. A complex set of highly differentiated taxes and subsidies, handled through a "price equalization fund," covered differences between the domestic prices of goods and the nominal national equivalent of the foreign trade price obtained by converting it into local currency at the arbitrary exchange rate. In these circumstances, producing firms generally had

little interest in foreign trade, which their superiors therefore specified for them in detailed plans.

In regard to foreign trade, reform proposals emphasized two related aspects: closer links between domestic and foreign prices, and some decentralization of decision making to producing units.<sup>21</sup> First, more realistic exchange rates should relate the general levels of domestic and world prices, while a reduction in taxes and subsidies on individual products should align the domestic price structure more closely to the world price structure. Then proceeds from exports and payments for imports could be accurately represented in enterprise accounts, directly affecting their sales, costs, and profits. Second, associations and/or enterprises should be given more authority to determine at least the composition of export production and also the right to negotiate directly with foreign firms, rather than through the intermediary of foreign trade enterprises subordinate to the ministry of foreign trade.

In most countries in the area, both types of proposals were partially implemented, though in different ways and to varying degrees.

Official exchange rates generally were not affected. Instead, shadow exchange rates (often euphemistically called "adjustment coefficients," "foreign trade multipliers," or "direction coefficients") were introduced, usually with different rates for the world market ("dollar") area and the CMEA ("ruble") area. Enterprises producing for export, or purchasing imports, now included these transactions in their financial accounts at the "foreign price equivalent," i.e., the foreign price translated into the national currency at the appropriate shadow rate.

However, in view of the domestic cost level and structure, full application of this new method of evaluating exports and imports would have led to large profits on some items and heavy losses on others and would have drastically altered the profitability of entire firms in fulfilling their assigned foreign trade plans. Hence, wide use of taxes and subsidies, differentiated by product and even by enterprise, continued. Also, it was expected that these shadow exchange rates would be adjusted from time to time to reflect changes in the relationship of the domestic and foreign price levels. But this policy instrument was not used flexibly and promptly. For example, in Hungary, as Portes' study in this volume explains, the authorities did change the "foreign trade multipliers" to reflect the devaluation of the dollar in 1971, but they were subsequently unwilling to revalue the forint enough to compensate for inflation on the world market beginning in 1973. Instead, they intervened further with export taxes and subsidies.

In most countries of the area, at least some producing units gained more contact with foreign customers or suppliers. For example, foreign trade enterprises were integrated into the new associations in Bulgaria, and into associations or industrial ministries in Romania. In the GDR, the network of foreign trade enterprises handling exports was reorganized so that each VVB association would have to deal with only one foreign trade enterprise, instead of several.

Such administrative changes can make it easier for producers to adjust specifications of exports to customers' requirements and to identify which imported machines best meet their needs. But the quantities to be traded, and the prices involved, are usually determined not by the association or enterprise itself but by the branch ministry and/or the ministry of foreign trade—particularly in regard to trade

<sup>21</sup> Brown 73 and Matejka 75.

with CMEA countries, which is arranged in high-level bilateral agreements covering quantities and prices.<sup>22</sup> Thus enterprises still receive foreign trade assignments, and their discretion is usually limited to decisions on some aspects of the assortment, within the specified global total.

#### 10. WORKERS' PARTICIPATION IN DECISIONMAKING

Communist countries have long had formal mechanisms for worker participation in decision making, both through trade union channels and through factory councils. Political speeches often call for workers to take an active role in the formulation, as well as the implementation, of enterprise plans. However, in practice workers seldom have had any significant influence on enterprise decision making—except in Yugoslavia under the system of “self-management” of enterprises introduced over 20 years ago.<sup>23</sup>

Only the Czech reform blueprint included genuine worker control of firms, though differing in important respects from the Yugoslav scheme.<sup>24</sup> Workers' management was implemented in some enterprises for a short period before the intervention of Warsaw Pact forces in 1968. Then it was terminated because it was viewed as a serious threat to Party control over the economy.

#### 11. AGRICULTURE

Economic reforms in Eastern Europe in the late 1960s primarily concerned the non-agricultural sectors, with only secondary attention to agriculture. The main approach to improving economic performance in agriculture was through policy measures rather than systemic changes. The latter involved chiefly organizational aspects.<sup>25</sup>

There were no striking organizational changes comparable to de-collectivization of agriculture in Poland in 1956. Instead, administrative and producing units in agriculture were reorganized in various ways. (a) In Bulgaria and Hungary the separate ministries of agriculture and food industry were merged. (b) Farm size was altered by combining smaller farms into larger ones in Hungary and the GDR, and by dividing larger farms into smaller ones in Romania. (c) Greater horizontal integration was accomplished by grouping farms into associations in Hungary, Poland, and Czechoslovakia, while the GDR stressed vertical integration. Bulgaria sought both horizontal and vertical integration by forming agro-industrial combines including farms and processing plants.

In most countries the government tried to boost agricultural output by various economic policy measures, such as raising prices and adjusting taxes and subsidies; increasing supplies of machinery, fertilizer, and other industrial inputs; and revising farmer compensation schemes to strengthen incentives. But farms still receive targets for sales to state procurement agencies, and the availability of off-farm inputs is controlled by state supply agencies.

<sup>22</sup> Tardos 73.

<sup>23</sup> Standard sources on “self-management” in Yugoslavia include Broekmeyer 70, Adizes 71, Vanek 72, and Wachtel 73. For recent developments, see Tyson's study in this volume.

<sup>24</sup> Rychetnik 68.

<sup>25</sup> Karcz 73 and Lončarević 75.

## 12. PRIVATE SECTOR

To meet consumer demands which state enterprises cannot satisfy, most East European countries permit various small private business activities, such as household plots of farmers, shops of watchmakers and tailors, family-run restaurants or bakeries, and the ownership and rental of private houses and apartments. The scope of this private sector changed relatively little as a result of the reforms.

In agriculture, restrictions on private plot activity were reduced in Bulgaria and Hungary by raising limits on livestock holdings and increasing supplies of feed and tools.

In the non-agricultural sectors, Romania eased restrictions on the amount of labor which private businesses could hire and also promoted private housing construction.

Hungary initially encouraged the growth of the private sector by allowing expanded activity by private artisans and widespread moonlighting by skilled workers, and also permitted agricultural cooperatives to start handicraft and light industry ventures. But by 1971 complaints about "profiteering," "money grubbing," and "materialism" led to higher taxes on private artisans, restrictions on moonlighting and ancillary non-agricultural operations of farms, new limits on real estate ownership, and new taxes on land transactions and private rentals.<sup>26</sup>

Most recently, at the end of 1976, Poland undertook to stimulate private artisan activity by increasing the availability of materials and business premises, raising the ceiling on the number of hired workers per firm, reducing taxes, and extending social security and medical care benefits to private businessmen.

*B. Reasons for Retrenchment*

Thus, the general pattern in Eastern Europe has been one of retreat, as the official reform blueprints—themselves less ambitious than the proposals of reformers—were at best only partially implemented. This section examines some of the principal reasons for retrenchment, including (1) interest group opposition, (2) internal inconsistencies among the reform measures, (3) excessive tautness (insufficient slack), (4) Soviet influence, and (5) developments in the world economy.

## 1. OPPOSITION

Only in Czechoslovakia (before the 1968 invasion) and in Hungary was the Party leadership strongly behind economic reform. Elsewhere in the area the Party leaders had only a diffident, ambivalent commitment to reform. In these circumstances, the staffs of the Party and government bureaucracies, fearing (correctly) that genuine reform would reduce their power, successfully impeded the execution of the relatively modest reforms. On the one hand, they urged caution, delay, and experiment in carrying out reforms. On the other, they recommended revision, curtailment, and reversal when the opportunity arose because contradictions among reform measures were perceived (Subsection 2), because it proved difficult to achieve ambitious

<sup>26</sup> The main issues are summarized briefly in Portes' contribution to this volume and are discussed in detail in Connor 75.

plans (Subsection 3), because the example and advice of the U.S.S.R. suggested a conservative approach (Subsection 4), or because developments in the world economy were unfavorable (Subsection 5).

In Hungary, where reform went much farther than in the other countries, the chief reason for the interruption of the momentum of reform in 1972 appears to have been the discontent of the urban blue-collar working class over the implications of reform for income differentiation and job security. The urban proletariat resented the faster rise in peasant incomes, the size of managerial bonuses, widening inter-enterprise earnings differentials from profit-sharing, and the ability of skilled workers like mechanics and electricians to obtain large secondary incomes from moonlighting. Less skilled manual workers were also alarmed by public discussions of the desirability of "removing brakes" on the further implementation of the reform by "eliminating unprofitable production" and "restructuring" production and employment. The authorities responded to the workers' concern by partial recentralization. They raised money wages for manual workers from central funds (rather than enterprise resources, as the reform provided), increased the powers of planning and price control bodies, put the 50 largest industrial firms under very close ministerial supervision, and tightened the regulation of enterprise investment.

## 2. INTERNAL INCONSISTENCIES

Reform blueprints typically suffered from internal contradictions, because some aspects essential for the successful operation of other aspects were not carried out in the correct way or at the right time. For example, performance indicators were altered to emphasize profit but output plans continued to require firms to produce some products at a loss. Or enterprises were permitted to retain profits for decentralized investment, but the materials allocation system was not relaxed to enable firms to acquire investment goods. As a result, various reform measures failed to yield the hoped for results—which strengthened the hands of opposition groups and either impeded the further implementation of reform or even reversed it.

The most critical dimension of reform from this viewpoint is the price system, because it should link various facets of decision making by providing a comprehensive and mutually consistent expression of relative values for use in evaluating alternatives in production, consumption, and investment. In the reforms of all the countries, fundamental deficiencies in the price system made it impossible to carry out successfully the changes which reformers sought in planning, allocation of materials, labor and wage regulation, performance indicators and incentives, and investment.

As explained above (Subsection A. 6), the central authorities continued to set producer goods prices as the sum of the planned branch average cost of production plus an arbitrary profit markup. But because such prices seldom reflected relative scarcities, the central authorities logically were unwilling in practice to abolish administrative allocation of material inputs and to eliminate obligatory enterprise targets for outputs and inputs. The authorities correctly feared that enterprise managers—motivated by material incentives to strive for good performance in terms of sales, value added, and/or profit calcu-

lated in these prices—would be likely to produce different output levels and mixes, using different input levels and mixes, than the authorities considered necessary. Nor could enterprises, and banks, decide what were the socially most desirable investments. Instead, to obtain the production and investment they wanted, the central authorities not only adjusted prices by a complex system of taxes and subsidies, but also continued to specify output assignments for, allocate machinery and materials to, control wages and labor use in, and determine investment by, associations and enterprises.

### 3. TAUTNESS

A “taut” plan is one whose fulfillment requires great exertion (and/or luck), whereas its opposite, a “slack” plan, can be achieved without special effort. In East European economies the central authorities commonly strive for taut plans for two related reasons: the desire to achieve rapid growth and structural change, and the belief that administrative pressure on enterprises is the best (or only) way to secure maximum performance from them.

However, some slack is essential to carry out reforms. Changes in administrative organization, planning methods, performance indicators, and incentives are bound to be disruptive until ministry and association officials, enterprise managers, and workers understand and adapt to them. During the transition period, economic performance in terms of output, sales, cost, and profit may not improve, and may even worsen. This is more likely to occur if reserves of materials, machinery, consumer goods, and convertible currencies have not been built up before the reform—to deal with foreseeable and unforeseeable difficulties in implementing sweeping new arrangements.

Keren has carefully analyzed the effect of tautness (slack) on the fate of economic reform in the GDR.<sup>27</sup> During the first four years of the New Economic System (NES) in 1964–68, the performance of the economy improved in regard to the rates of growth of national product and exports, the structure of net product, the balance between supply of and demand for consumer goods, and the reduction in the build-up of unfinished construction. This occurred because of a change in planning strategy from tautness to slack as well as because of the introduction of changes in organization, planning, and management.

But when the GDR authorities returned to taut plans in 1969–70, recentralization occurred in various respects, essentially terminating the NES in fact, if not formally. Whereas responsibility for preparing material balances could be delegated to associations and enterprises when plans were slack, tauter plans meant that superior organs had to handle more balances. This would happen even without formal recentralization, because an over-committed balance at a lower hierarchical level inevitably led to appeals to higher levels by users whose allocations had been cut. Tight balances also caused the reshuffling of planned flows and abrogation of contracts—causing a return to “contracts based on balances” (and flows decided from above), rather than “balances based on contracts” (and flows determined by enterprises themselves). Further, taut plans altered the effective performance indicators and incentives, by inducing neglect of cost, profits,

<sup>27</sup> Keren 73, especially pp. 570–72 and 581–82.

and quality in the attempt to fulfill output assignments, and by encouraging managers to amass reserves of labor, materials, and production capacity to prepare for the higher plan targets expected in the future under the "ratchet principle." Finally, taut plans altered the influence of the price system on production. A taut plan for a sector puts a large premium on its capacity and raises shadow quasi-rents and marginal costs high above normal average costs (on which prices are based). Therefore, the tauter the plan, the less will prices convey scarcity information and guide profit-seeking firms correctly in their choice of inputs.

Polish experience also shows that reform measures seldom can survive conditions of stress. According to the Polish economist Kleer, reform involved reduction in the number of directive indicators handed down from higher to lower levels, but—

these were not irreversible changes. When, for whatever reason (a poor harvest, difficulties in foreign trade, excessive investment, etc.), difficulties were heightened, the rights granted were "withdrawn." This was revealed in a growing number of commands in the form of directives or at least informational directives, allocation of raw materials and semifinished goods, greater wage discipline, etc.<sup>28</sup>

#### 4. SOVIET INFLUENCE

The U.S.S.R. has influenced economic reforms in Eastern Europe in several ways: (a) through the example of its own reform, (b) through intervention in Czechoslovakia in 1968, and (c) through its efforts to coordinate production, investment, and trade in CMEA.

(a) The "minor" or "partial" reform countries followed the lead of the U.S.S.R. in regard to reform discussions, reform blueprints, and the pattern and degree of implementation in many (though not all) respects.<sup>29</sup>

This is illustrated by the similarity of the GDR's NES to the Liberman proposals in the U.S.S.R. The latter advocated devolving responsibility for smaller decisions to lower hierarchical levels, while retaining at the top control over more important decisions—by giving enterprises more freedom of maneuver within a centrally determined plan, on whose fulfillment bonus payments depended. The very publication of the Liberman discussion in the U.S.S.R. beginning in 1962 was seen as a green light for a similar debate in the GDR, and many details of the NES mirrored specific Liberman proposals.<sup>30</sup>

But as the limited scope of economic reform in the U.S.S.R. became clear, the East European countries (with the exception of Hungary, and of Czechoslovakia through 1968) followed the conservatism of the Soviet reform in regard to such critical aspects as the price system, obligatory plan indicators, central control over supply allocation and thus investment, and regulation of enterprise wage funds.

(b) Through the intervention of Warsaw Pact forces in Czechoslovakia in 1968, the U.S.S.R. made clear that it would not tolerate an economic reform in Eastern Europe (outside Yugoslavia) which gave market forces a dominant role in guiding the economy, introduced workers' management, and substantially weakened the Party's control of economic, political, and social life.

<sup>28</sup> Kleer 73, pp. 11-12. See also Fallenbuchl's paper in this volume.

<sup>29</sup> On Soviet experience, see, for example, Schroeder 73, Adam 73, and Gorlin 76. The establishment of the association link in the administrative hierarchy, discussed by Gorlin, is one aspect in which the U.S.S.R. appears to have been influenced by East European practice.

<sup>30</sup> Keren 73, pp. 555-56.

Although the Hungarian reform was also of the "comprehensive" type, it proved acceptable to the U.S.S.R. because it excluded workers' management, retained the unified Party's leading role in society, and assured the primacy of the U.S.S.R. and other CMEA countries in Hungary's external political and economic relations.

(c) Thus, the U.S.S.R. evaluated economic reform in Eastern Europe in terms of the implications for Soviet political and economic control of the area. The U.S.S.R. believes it is easier to achieve the bilateral and multilateral production, trade, and investment relations it desires in CMEA (1) if member countries' internal planning and management systems are essentially similar, and (2) if these similar systems involve little devolution of decision making, since decentralization would make it more difficult to negotiate and implement CMEA agreements.<sup>31</sup>

##### 5. DEVELOPMENTS IN THE WORLD ECONOMY

When a nation experiences disturbances in its foreign economic relations—for example, inflation in countries supplying imports or recession in countries buying exports—there is usually a centralized response, in the form of adjusting exchange rates, exchange controls, tariffs, import quotas, and internal taxes and subsidies. Thus, adverse developments in the world economy can be expected to retard or reverse decentralizing economic reforms.

In most of Eastern Europe, economic reforms had stalled before the expansion of East-West relations early in the 1970s made these nations more vulnerable to inflation and recession in the world market—which occurred following the Arab oil embargo in 1973 and the subsequent OPEC-dictated increases in oil prices.

However, these developments did affect the course of reform in Hungary and Poland. In Hungary, the New Economic Mechanism (NEM) of 1968 had assumed a stable world market—not one in which rapid import price rises outstripped export price increases, leading to a severe deterioration in the terms of trade, first with developed and less developed market economies in 1973–74 and then within CMEA in 1974–75. The authorities had to face the conflict between their desire for approximate stability in domestic producer and consumer prices, on the one hand, and the reform's principle that changes in external markets should affect enterprises' production and use of inputs through changes in prices. The authorities chose the former alternative, resorting to large subsidies and export taxes to preserve the prevailing pattern of enterprise activities. As a result, according to a leading Hungarian economist, contrary to the intent of the reform, "the enterprises were interested in successful negotiations with the state organs responsible for taxes and subsidies rather than in adaptation to market tendencies."<sup>32</sup>

In Poland, as Fallenbuehl's paper in this volume explains, inflation on the world market was a major cause—along with internal inconsistencies and excessive tautness—of the retrenchment in Gierek's reforms. On the one hand, foreign inflation raised import prices, but because of the political importance of price stability, import prices rises were mostly offset by large increases in subsidies. On the other

<sup>31</sup> See Marsh 76 for a detailed discussion of these issues.

<sup>32</sup> Tardos 75b, p. 287.

hand, to induce organizations to produce for export, the reform had included the principle of calculating a firm's exports at so-called "realization prices" directly related, through foreign exchange coefficients, to the actual prices in foreign currencies. Hence, higher prices in foreign markets raised the amount of sales, value added, the wage fund, and other enterprise funds. To prevent firms from enjoying windfall increases in these funds due not to their efforts but to changes in the world market, "normatives" for allocating money to these funds were reduced, and part of the funds was frozen or transferred to the control of ministries.

#### IV. CONCLUSIONS

The reform movement in Eastern Europe emerged because of dissatisfaction with the nature and results of the traditional Soviet-type economic system installed in the area after World War II. The struggle between pro- and anti-reform forces varied by country and led to different reform blueprints, incorporating diverse concepts of "decentralization" and dissimilar implementation strategies.

Throughout the area, there was a retreat from reform—earlier, faster, or farther in some countries than others. The reasons included interest group opposition, internal inconsistencies, insufficient slack, Soviet influence, and developments in the world economy. Only Hungary now has a significantly different economic system, although formal and informal central intervention in the Hungarian economy is much greater than intended when the NEM was introduced in 1968.

As a result, it is not possible to determine whether and how much economic reform—in the sense of comprehensive mutually consistent decentralizing systemic changes—can improve economic performance. In most countries, economic reform was not really carried out, or at best was implemented partially for a short period, while internal economic policies—regarding plan tautness or living standards—and the external environment were changing.<sup>33</sup>

The problems of unsatisfactory growth rates, balance of payments difficulties, lagging technological progress, and popular discontent with living standards continue throughout the area. In their search for ways other than systemic change to improve economic performance, the regimes of these countries have turned their attention to foreign trade and investment.

Through expanded East-West economic relations, stemming from Soviet-U.S. "détente," the East European countries (like the U.S.S.R.) hope to import Western machinery and equipment, licenses for processes, and in some cases consumer goods—in order to expand output, stimulate technological progress, increase exports, and satisfy demands of their populations. However, as other studies in this volume explain, these hopes are constrained by the inability to increase hard-currency exports fast enough. At first, the gap was covered by Western credits, but outstanding indebtedness is now large—particularly for Poland but also for other countries—and servicing the debt absorbs a large and rising portion of export earnings. Hence, these countries are

<sup>33</sup> On problems in evaluating the effects of economic reform, see Zielinski 73, pp. 298-308.

especially interested in "industrial cooperation" agreements with Western firms which include selling at least part of the output to hard-currency countries.

As Fallenbuchl argues in his contribution to this volume, some systemic reform may be helpful or even necessary to take full advantage of Western machinery and technology and to expand exports to pay for them. For example, changing the price system to reflect scarcities more accurately and valuing exports and imports at the proper domestic equivalent of their foreign prices would lead to more sensible central decisions on the composition of exports and imports and the pattern of investment. These measures could also induce firms to increase the quantity and quality of exports and to economize on the use of imports—provided that performance indicators and incentives were adapted to give adequate and assured rewards to the personnel of firms accomplishing these difficult tasks.

However, given the current and prospective balance of payments situations of these countries, the central authorities are likely to retain close control over hard-currency exports and imports, as well as negotiations with foreign banks for credits and with foreign firms for joint ventures. Thus, little devolution of authority over these matters to enterprises and associations is probable.

Furthermore, the East European economies will remain heavily involved in CMEA, both because of Soviet pressure and because their ability in the short- or medium-term to restructure their economies toward more trade with the West is limited. Also, after their sobering experience with fluctuations in prices and quantities on the world market since 1973, they appreciate more keenly the advantages provided by the stability of CMEA trade agreements. But, as explained above, integration in CMEA discourages economic reforms which differentiate the member countries' economic systems and give enterprises autonomy which complicates fulfillment of centrally-negotiated agreements.

Thus, expanded trade and investment relations with the West and with CMEA are viewed more as alternatives than as comparisons to internal economic reforms.

### I. INTRODUCTION

At the beginning of 1975, the prices which the Soviet Union and the countries of Eastern Europe used in their trade with one another underwent sweeping revision. The timing as well as the scope and size of the changes was noteworthy, since no major overhaul of intra-CEMA trade prices had been scheduled until the beginning of 1976.<sup>1</sup> Prices, at the time of the change, were supposed to have remained fixed from 1971 through 1975, with price relationships guided by the average of so-called world prices in 1965-69.

The premature institution of a new set of price relationships in intra-CEMA trade was accompanied by an announcement of a new method of averaging world prices as the prime determinant of intra-CEMA trade prices. Formerly, prices for a prescribed interval—a five-year plan period—were based on world prices for a specified preceding period. Starting in 1975, world prices were to be applied more flexibly, with intra-CEMA trade prices in any given year to be based on world prices for the immediately preceding five years.<sup>2</sup>

There were also indications that there would be a marked expansion of above-plan trade, a large portion of it apparently to be conducted on a hard currency basis and at current world prices rather than through the barter type arrangements based on lagged world prices that characterize most intra-CEMA trade.

This paper will address itself to two of the many questions raised by the changes summarized above. First, it will examine why the price

\* We would like to express particular appreciation to Mark Allen, Lawrence J. Brainard, and Claus Wittich for their assistance. Not only did we find their written work, published and unpublished, most helpful, but we greatly benefited from the insights they shared with us in personal conversations.

We would also like to thank James S. Bodnar, George T. Boutin, Harry Kopp, and James A. Treichel for their helpful comments. Our thanks go also to John R. Patton for so efficiently performing required computer work. We are also very grateful to Shauna Gunderson for so flawlessly and speedily typing the manuscript.

The authors of course assume full responsibility for any errors or flaws in this paper.

<sup>1</sup> CEMA stands for the Council of Mutual Economic Assistance. Its members include the Soviet Union, Bulgaria, Czechoslovakia, the German Democratic Republic (GDR), Hungary, Poland, Romania, Cuba, and Mongolia. The stated purpose of CEMA, which was created in 1949, is to promote integration and coordination of economic activities among the member countries. (CEMA also goes by the initials COMECON.)

<sup>2</sup> However, for some commodities (notably oil), it was indicated that the reference period for 1975 would be 1972-74 rather than 1970-74.

changes were made when they were and with what effect. It will then explore the somewhat broader issue of whether the new pricing formula and the alleged expansion of intra-CEMA hard currency trade signal basic changes in the intra-CEMA trading system.

Our main conclusions can be summarized as follows:

- Intra-CEMA trade prices were prematurely raised at the initiative of the Soviet Union to bring the USSR's terms of trade vis-a-vis Eastern Europe more in line with what they would have been if based on current, rather than lagged, world prices. The immediate effect of the rises in CEMA prices was to improve the USSR's terms of trade substantially but still by much less than would have been the case if current world prices had been applied.
- The new price formula will not bring about fundamental changes in the intra-CEMA trade system and indeed could complicate the price formation process further without achieving compensating improvements.
- Hard currency trade within CEMA does not appear to have expanded very much and is not likely to increase to the point where it will significantly alter the basically bilateral, barter-like character of trade among CEMA countries.

Our discussion of how and why these conclusions were reached will be preceded by a brief description of the operation of intra-CEMA trade.

## II. MAIN FEATURES OF THE INTRA-CEMA TRADING SYSTEM

Trade among the Soviet Union and the countries of Eastern Europe is conducted for the most part through bilateral barter arrangements, generally formulated in five-year and annual trade agreements between pairs of countries. There is considerable emphasis on balancing trade and, in fact, annual bilateral imbalances within CEMA are generally small and are even smaller for five-year plan periods as a whole.

Annual or even five-year plan balance on trade account is not, however, a necessary condition for intra-CEMA bilateralism, which refers essentially to the fact that overall payments in external economic relations within CEMA flow almost exclusively in bilateral channels. Bilateralism prevails basically because it greatly reduces uncertainty regarding allocation of resources that could be disruptive to centrally planned economies. Under multilateralism, a claim that one country obtains through trade or other transactions with a second country can be used to buy goods and services in a third country. However, if the third country is one with a planned economy, to the extent that the purchase order is unexpected, it is likely to force an unforeseen reallocation of resources which could jeopardize the achievement of plan targets, an obviously unwelcome development in such an economy.

Thus, for example, if one CEMA country runs a surplus in trade with another CEMA country in a given year, it is unlikely to be able to use the claim thus obtained to buy goods in a third country. Instead, its claim, in general, could only be exercised through subsequent purchases of goods and/or services in the country in which the claim originated—for instance, by running an offsetting trade deficit in the

future. In other words, multilateralism within CEMA is conspicuous by its absence or, at best, by its very limited presence.<sup>3</sup>

Making the climate for multilateralism within CEMA even more unfavorable is the fact that the goods that a third country would make available, if it was willing to make them available at all, would probably be so-called "soft goods." These are goods (mostly manufactures) that are overpriced in CEMA trade in the sense that they are bartered at ratios much more favorable than CEMA countries could obtain if they sold these goods in Western countries. The likelihood that an order for so-called hard goods would be accepted is slim. Hard goods refer to commodities (generally, raw materials) that tend to be underpriced in intra-CEMA trade and are readily saleable in the West at going market prices.<sup>4</sup>

Thus, even though the institutional machinery for it exists,<sup>5</sup> multilateralism on any but the most minor scale is all but precluded within CEMA. Since countries can make only the most restricted use of balances in transferable rubles<sup>6</sup> outside of bilateral channels, they have no incentive to accumulate them and indeed seek to avoid accumulating them.<sup>7</sup>

What about the prices at which goods are traded within CEMA? For systemic reasons, domestic prices of traded goods cannot be translated into meaningful intra-CEMA trade prices. The basic problem is that market forces play a negligible role in determining the allocation of resources. The situation is not one of a multitude of independently operating firms and individuals in many countries buying and selling in essentially free markets, thus allowing market forces to determine domestic prices and the exchange rates that govern international transactions. Instead, even in the economically more liberal Eastern European countries, administrative determination of resource allocation prevents prices from adequately reflecting relative scarcities, as is the case in market economies. Furthermore, market forces, as understood in the West, play virtually no part in determining intra-CEMA trade flows. Rather, these flows are determined, for the most part, by the central authorities of pairs of countries bargaining with each other over what to trade and, in effect, the ratios at which a given good or group of goods should be exchanged for another good or group of goods. This procedure likewise prevents the emergence of a realistic or equilibrium exchange rate. A nominal commercial exchange rate exists for the currency of each CEMA country vis-a-vis the currency of every other country, but these exchange rates play no role in the price formation process in the bilateral barter-type trade that predominates within CEMA.

<sup>3</sup> Perhaps 5 percent of intra-CEMA trade is settled on a multilateral basis.

<sup>4</sup> For a discussion of hard and soft goods, see Mark Allen, "The Structure and Reform of the Exchange and Payments System of Some East European Countries," International Monetary Fund Staff Papers, XXIII:3 (November 1976).

<sup>5</sup> The Bank for International Economic Cooperation (IBEC) was put into operation in 1964 in large part to foster multilateralism in CEMA. IBEC is equipped to provide the clearing and credit services that would facilitate multilateral settlements. Settlement of trade transactions among CEMA countries is in fact conducted through IBEC, but settlement continues to be on predominantly bilateral basis.

<sup>6</sup> The transferable ruble is the unit of account in which transactions conducted through IBEC are denominated and in which the claims and liabilities of IBEC are denominated. More about the transferable ruble below.

<sup>7</sup> The phenomenon of transferable ruble balances not being able to buy goods except those designated in trade plans is called "commodity inconvertibility." See Franklyn D. Holzman, "International Trade Under Communism—Politics and Economics," (New York, Basic Books, Inc., Publishers, 1976).

To solve the problem of deciding at what ratios physical quantities of different goods should be exchanged for one another, CEMA countries look to world market prices for guidance.

Conceptually, there is an element of rationality in this procedure, since the countries of Eastern Europe, and even the Soviet Union, despite the imposing size of its economy, play a very small role in world trade for most commodities. They therefore exert little influence on world markets and, in fact, in trade with the West buy and sell at prevailing prices. They are, in economic shorthand, price takers, not price makers. However, the absence of domestic prices and exchange rates that adequately reflect cost and demand factors makes it difficult for CEMA countries to ascertain what goods they can most advantageously buy and sell. This problem resort to world markets cannot solve.

How specifically to apply world prices, furthermore, is a contentious matter. Even after allowance is made for differing transportation costs, prices of even homogeneous products, because of market imperfections, may vary from market to market. For heterogeneous products—many manufactures, particularly machinery—the search for suitable world prices is much more difficult, with disagreement over what constitutes an appropriate noncommunist counterpart product highly likely.

Application of world prices also requires adjustments that take into account transportation costs. This is accomplished through use of agreed upon formulas.<sup>8</sup>

The determination of what world prices are to be used, and with what adjustments they are to be applied, is made in the many separate negotiations of trade agreements that take place annually between pairs of CEMA countries. The terms of trade between pairs of countries will thus depend to a considerable degree on the relative bargaining strengths and skills of the trade partners. One consequence of setting prices in this manner is the phenomenon of multiple prices for the same good, the price varying from agreement to agreement.

The world prices finally agreed upon include adjustments not only for transportation costs, but according to CEMA countries, to eliminate "seasonal, cyclical, speculative, and monopolistic factors." What, if anything, all this means and how the adjustments are made is not clear. Presumably, though, using an average of prices over an interval of several years as a reference period, as CEMA has done and continues to do under the new formula, would eliminate or reduce the influence of cyclical, seasonal and speculative factors.

Though world prices provide the yardstick by which intra-CEMA trade prices are established, intra-CEMA trade is reported in terms of a unit of account called the transferable ruble. This is achieved by converting the world prices used into TR's through application of official exchange rates of the TR vis-a-vis other currencies. (TR exchange rates are in fact determined by the official exchange rates of the Russian ruble with respect to other currencies.)<sup>9</sup>

<sup>8</sup> The basic formula calls for addition to the base price of half of what it would have cost to ship the good to the buyer from the market where it would presumably have been bought in the absence of a CEMA-country supplier.

<sup>9</sup> It should be stressed, however, that the TR is little more than a unit of account. It does not fit the definition of money, its use and value as a medium of exchange and a store of value being virtually nil. For an excellent discussion of the TR's lack of the properties associated with money, see Franklyn D. Holzman, "Ruble Convertibility," Cambridge, Mass.: Russian Research Center, Harvard University, 1976.

### III. THE 1975 PRICE CHANGES

The basic reason for switching to a new formula for applying world prices to help set intra-CEMA trade prices in 1975 was that the cost of the old formula to the Soviet Union had become excessive. The USSR, the dominant member of CEMA, had become the biggest loser, in opportunity cost terms, from the explosive rise in prices of raw materials, notably oil, in 1973 and the first part of 1974.

In a period characterized by relatively stable world prices—where, furthermore, trade with the non-communist world is not of crucial importance—using world prices from some fixed previous period as the reference point for prices in an extended subsequent period is reasonable. It provides the economic planners with the stability and certainty they so highly treasure without imposing serious economic penalties.<sup>10</sup>

In the 1970's, however, the conditions of price stability and lack of concern about trade with the West were not met. This was a period of volatile price movements that coincided with a drive by the Soviet Union and most of the countries of Eastern Europe to expand trade with the West to help modernize their economies. Consequently, the convenience of prolonged price stability came increasingly into conflict with economic rationality. The gap between the terms on which the Soviet Union sold oil in the West and on which it sold it in Eastern Europe was the main reason for the Soviet-engineered institution of a new price formula. The price changes introduced in early 1975 in intra-CEMA trade consisted primarily of increases for a broad range of commodities, with the largest boosts, proportionately, being for fuels and other raw materials.

Soviet terms of trade with respect to the six East European countries during the first four years of the Five-Year Plan period 1971-75 changed very little, as measured by two terms of trade indices compiled by one of the authors of the present paper. One index was constructed from official Soviet data on increases in the value and volume of Soviet trade with CEMA countries. The other—using a method devised by Edward A. Hewett—was compiled on the basis of unit values in the USSR's trade with its Eastern European trade partners. The unit values were computed from official Soviet trade data and then weighted by appropriate values of Soviet trade, also from official sources.<sup>11</sup>

That the changes in the Soviet Union's terms of trade vis-a-vis Eastern Europe in 1971-74 were insignificant is to be expected, of course, given that intra-CEMA trade price relationships during this period were supposed to have remained stable, on the basis of the 1965-69 averages of world prices.

The high opportunity cost of this terms of trade stability is indicated by calculations, utilizing UN data on world export prices, that the Soviet terms of trade from 1971-74 might have improved by 30 to 40 percent if changes in Soviet intra-CEMA trade prices had moved in conformity with changes in world trade prices.<sup>12</sup>

<sup>10</sup> Prices of individual items do change during periods of supposedly fixed prices, but these alterations pretty much cancel out in that they do not significantly change the terms of trade between pairs of countries. Such price revisions are therefore devoid of any substantive economic significance.

<sup>11</sup> For a detailed description of these indices, see Martin J. Kohn, "Developments in Soviet-Eastern European Terms of Trade, 1971-75," in "Soviet Economy in a New Perspective" (Washington, D.C., Joint Economic Committee, Congress of the United States, 1976). Hewett's unit value based terms of trade indices are presented in Edward A. Hewett, "Foreign Trade Prices in the Council For Mutual Economic Assistance" (London, Cambridge University Press, 1974).

<sup>12</sup> Kohn, "Developments in Soviet-Eastern European Terms of Trade, 1971-75," p. 76.

The overriding cause of the disparity between the actual movements in the USSR's terms of trade vis-a-vis Eastern Europe and what these movements would have been if current world prices had prevailed in intra-CEMA trade was the quantum jump in the price of oil in 1973-74. Crude oil prices at the beginning of 1975 were roughly four times higher than they had been 15 months earlier. Oil, mostly in crude form, has long been a major Soviet export to Eastern Europe (except for Romania). During the first four years of the Five-Year Plan 1971-74, oil sales accounted for 10.6, 11.4, 12.0, and 12.2 percent respectively, of the total value of Soviet exports to the Eastern European members of CEMA. Clearly, therefore, maintaining oil prices unchanged was costly to the USSR.

The undoubted importance of oil in impelling the Soviet Union to revamp CEMA trade prices ahead of schedule is underscored by evidence that its terms of trade vis-a-vis Eastern Europe as measured by current world prices would have improved negligibly if at all if it were not an exporter of oil.<sup>13</sup> Furthermore, there would apparently have been little advantage to the USSR to change from a 1965-69 to a 1970-74 price reference base in the absence of oil exports. This is indicated by computing what the USSR's terms of trade vis-a-vis Eastern Europe would have been if 1970-74 or 1972-74 rather than 1965-69 world prices had been used, first when Soviet exports and imports of fuel are included and then when they are excluded. Specifically, UN world export price indices covering the intervals in question were weighted by the appropriate values of Soviet-Eastern European trade in 1974 (when 1965-69 world prices were still the reference period) to yield export and import price indices from which the terms of trade were then computed. The results—which, along with the method used to derive them, are presented in Appendix 1—show that if 1970-74, rather than 1965-69, world prices had been in effect in 1974, Soviet export prices to Eastern Europe would have been 60 percent higher, import prices 41 percent higher. The terms of trade—and it should be understood that we are referring here to hypothetical terms of trade—would thus have increased by about 13 percent in the USSR's favor by using the prices of the later instead of the earlier period. When the fuels component of these indices are removed, however, there is virtually no change in the terms of trade, with the rise in export prices reduced to 40 percent and the rise in import prices to only 38 percent. (Data limitations required use of an export price index for all combustible fuels to be used as a proxy for oil in computing these indices. As Table 4 in Appendix I suggests, this probably had only negligible effects on the results.)

The comparison of 1972-74 to 1965 prices shows an improvement in the USSR's terms of trade of 20 percent when fuels are included, Soviet export prices rising by 89 percent, import prices by 57 percent. But, as with 1970-74 prices, the terms of trade gain for the Soviet Union drops to practically nothing when fuels are removed from the calculations, export prices rising by 56 percent, import prices by 53 percent.

Oil is also a major Soviet export to non-Communist countries and, as a result of the 1973-74 price rises, has become the USSR's major

<sup>13</sup> Kohn, "Developments in Soviet-Eastern European Terms of Trade, 1971-75," pp. 75-76.

earner of hard currency.<sup>14</sup> Consequently, one of Moscow's motives for instigating the 1975 price changes in intra-CEMA trade was almost certainly to discourage Eastern European demand for Soviet oil. However, the approximate doubling of Soviet oil prices still permitted Eastern European countries to buy oil from the USSR on considerably more advantageous terms than from non-communist oil producing countries. So the inhibiting effect was presumably minimal. However, it may increase, since, under the new pricing formula, for several years relatively low prices of earlier years will drop out of the five-year periods used to compute oil prices and be replaced by much higher values for later years. However, though the advantage to Eastern Europe of buying oil from the USSR may decrease, it will not disappear. OPEC oil prices continue to rise, and it is unlikely that the rate of increase will lag behind the rate of increases in the prices of East European exports to the USSR.

A far more effective means to discourage Eastern European demand for Soviet oil would be to charge prevailing market prices. The Soviets are in fact almost certainly doing this, but evidently only for a relatively small proportion—perhaps 10 to 15 percent—of their oil sales to Eastern Europe. The Soviets are apparently resigned to remaining Eastern Europe's major source of oil. Data on future plans suggest that Soviet oil shipments to Eastern Europe will be about 80 million metric tons in 1980, about a 25 percent increase over the slightly more than 63 million tons exported there in 1975.<sup>15</sup>

By how much did the price changes of early 1975 improve the USSR's terms of trade? Indices compiled using unit values computed from official Soviet trade data as proxies for foreign trade prices show an improvement of about 11 percent when 1974 value weights are used and about 14 percent with 1975 value weights.<sup>16</sup> The results are shown in Table 1 below:

TABLE 1.—SOVIET-EASTERN EUROPE TERMS OF TRADE, 1975 VIS-A-VIS 1974  
[1974=100]

	Soviet export prices		Soviet import prices		Terms of trade index	
	1974 weights	1975 weights	1974 weights	1975 weights	1974 weights	1975 weights
Bulgaria.....	139	156	130	137	107	112
Czechoslovakia <sup>1</sup> .....	142	144	123	121	115	119
German Democratic Republic.....	147	154	121	125	121	125
Hungary.....	140	150	127	129	110	116
Poland.....	141	151	139	144	102	104
Romania.....	134	143	132	138	102	105
6 countries combined.....	142	151	128	132	111	114

<sup>1</sup> An arbitrary index number was used to reflect the change in unit values from 1974 to 1975 of Soviet imports of metals and metal ores from Czechoslovakia. The U.S.S.R. publishes only the total value of such imports, giving no physical quantity figures. Because of their heavy weight in total Soviet imports from Czechoslovakia—15 percent in 1974, 12 percent in 1975—it appeared that assigning an arbitrary but reasonable estimate of the change in the unit value of imports of metals and metal ores would distort the overall index of unit value changes in Soviet imports from Czechoslovakia far less than would exclusion of imports of metals and metal ores entirely. The index number assigned was that for the change in unit values of the corresponding Soviet exports to Czechoslovakia (Soviet trade classification groups 24 through 27).

Source: "Vneshnyaya Torgovlya SSSR v 1975 g."

<sup>14</sup> About \$4 billion in 1976, roughly 40 percent of total Soviet revenue from hard currency exports. In 1972, before the oil price explosion, oil export earnings were only \$555 million, 20 percent of the value of total Soviet hard currency exports.

<sup>15</sup> Eastern Europe (except for Romania) is heavily dependent on the USSR for oil. The proportion of crude oil imports accounted for by the USSR ranges from about 75 percent for Hungary to over 95 percent for Czechoslovakia. Of the five Eastern countries that import oil from the USSR, only Hungary produces crude of its own. Hungary's oil output equals slightly less than a quarter of its imports.

<sup>16</sup> The method by which these indices were compiled is essentially that used in Hewett, *Foreign Trade Prices in the Council For Mutual Economic Assistance*. The results in Table 1 were computed using the method employed in Kohn, "Developments in Soviet-Eastern European Terms of Trade, 1971-75," pp. 78-80.

The results in Table 1 for the six countries combined is roughly in line with the computation of a 10 percent improvement in the USSR's overall terms of trade vis-a-vis Eastern Europe that can be derived from official data on changes in the value and volume of trade from 1974 to 1975.<sup>17</sup>

Clearly, the improvement in the USSR's terms of trade in 1975 fell far short of the improvement that application of world price changes since 1971 would have dictated. In this respect, the Soviet initiated price changes of early 1975 were relatively moderate, implying an effort to minimize the adverse effect of the increased prices on the economies of Eastern Europe. However, if the new price formula is rigorously applied, Soviet terms of trade, in all probability, will continue to improve for several years. Furthermore, though restrained in terms of what they might have been, the 1975 price changes may well have had a markedly adverse effect on four of the six countries of Eastern Europe. Romania and Poland, as raw materials exporters themselves, were little affected by the price revisions. But the GDR, Czechoslovakia, Hungary and Bulgaria would have had to increase their volume of exports by substantial amounts to maintain a given volume of imports from the USSR, their most important trade partner. To express the negative impact for these four countries in rough quantitative terms, the physical volume of imports that they could obtain from the USSR in return for what they actually exported to the USSR in 1975 was lower in 1975 compared to what it would have been in 1975 by amounts equivalent to roughly 1 percent of GNP for the GDR, Bulgaria, and Hungary, and over one-half of 1 percent in the case of Czechoslovakia. These are not negligible amounts.

#### IV. IMPLICATIONS OF THE NEW PRICING FORMULA

The new formula reflects an attempt by Moscow to resolve the conflict between advancing its own economic goals and safeguarding economic, and thereby, political equilibrium in Eastern Europe. Soviet economic interests would have been best served by moving from 1965-69 to current world prices in early 1975. But such a step would have been not only an abrupt departure from past practice, but more important, a severe economic blow to all Eastern European countries save Poland and Romania.

However, though in effect a compromise solution, introduction in 1975 of a lagged but annually changing reference interval was apparently to the USSR's advantage. Although it does not permit the Soviets to bring CEMA and world trade prices into line at a single stroke, it will almost certainly produce a steady improvement in the

<sup>17</sup> Kohn, "Developments in Soviet-Eastern European Terms of Trade," p. 74 and pp. 76-77. The 10 percent improvement in the USSR's terms of trade computed from the value and volume data are more comparable to the unit-value based results using 1975 value weights than the results using 1974 value weights. This is so because a terms of trade index derived by using a value index deflated by a volume index using base year price weights (as is true of the Soviet trade volume index) yields a terms of trade index weighted by terminal year quantities:

$$\left( \frac{\sum p_{1i} q_{1i}}{\sum p_{0i} q_{0i}} \right) \left( \frac{\sum p_{0i} q_{0i}}{\sum p_{1i} q_{1i}} \right) = \frac{\sum p_{1i} q_{1i}}{\sum p_{0i} q_{0i}}$$

where:

$p_{0i}$  = the price of the  $i$ th item in the base year,

$p_{1i}$  = the price of the  $i$ th item in the terminal year,

$q_{0i}$  = the quantity of the  $i$ th item in the base year,

$q_{1i}$  = the quantity of the  $i$ th item in the terminal year.

USSR's terms of trade vis-a-vis Eastern Europe for several years. Moreover, it established the principle of continuous adjustment of CEMA prices to reflect changes in world prices.

However, the lagged moving average system may cause as many problems as it solves. With a lag of five years, there is substantial risk, in a period of large and rapid price changes, that intra-CEMA trade price relationships will move out of line with world price relationships. At the same time, the procedure of changing prices every year presumably is administratively costly and threatens to make the price setting process more disorderly than it was. As stated above, world prices are not rigorously or systematically applied but serve as reference points and bargaining tools. With price setting now an annual affair, the apparently enormous amount of time and effort always required to agree upon prices is likely to have been multiplied many times over, with the likelihood of an increased frequency of such phenomena as multiple prices for the same item. Hungarian economist Sandor Ausch noted, with reference to the pre-1975 system, that "negotiations preceding general price revisions are prolonged through several years . . ." <sup>18</sup>

Only scant information is available about the application of the new formula. However, there are some indications that it is frequently used in a loose, improvisational manner. It was never made clear, for instance, which commodities in 1975 were to be priced according to the 1970-74 average, which according to the 1972-74 average. In fact, we have been told that the actual situation was one of considerable confusion, with reference intervals in addition to the officially reported ones being employed.

Oil offers an example of how the formula may be rigorously and flexibly applied at different times. In 1976, the price of oil charged by the USSR to Eastern European buyers apparently rose by about 8 percent. This is in keeping with what one would have expected in terms of the formula. In 1975, oil was supposedly priced according to average world prices for 1972-74; in 1976, according to the 1971-75 average. The price of Middle Eastern oil that the Soviets presumably would use as a world price reference did in fact average 8 percent higher in 1971-75 than in 1972-74.

In 1977, however, there are indications that the formula is not being adhered to. Middle Eastern oil prices averaged 30 percent more in 1972-76 than in 1971-75. But the price of Soviet oil exports to Hungary in 1977 has been raised by only 22.5 percent. This suggests that the Soviet Union is retreating from strict application of the formula, perhaps to help ease economic strains in Hungary.

Admittedly, this interpretation of the 22.5 percent boost is highly speculative. Other explanations can be offered. For example, Hungary could be changing the prices of its exports to the USSR by less than called for in the formula so that the terms of trade between Hungary and the USSR will move in accordance with what the formula would indicate.<sup>19</sup> However, the fact that the price increase appears to have been exactly three-fourths of the rise called for by the formula raises

<sup>18</sup> Sandor Ausch, "Theory and Practice of CMEA Cooperation," (Budapest: Akademiai Kiado, 1972), p. 90.

<sup>19</sup> For a discussion of the increase in the price of Soviet oil exports to Hungary, see Radio Free Europe Research, Harry Trend, "First Announcement of Price to be Paid for Soviet Oil in 1977," RAD Background Report/7 (Eastern Europe), 11 January 1977.

the suspicion that a concession of some sort is being made. This would be consistent with Soviet efforts to avoid intensification of economic stresses that could add to the political unrest evident in parts of Eastern Europe at present. The clearest demonstration of this policy was the one billion ruble credit the USSR extended to Poland in late 1976. But raising prices by less than prescribed amounts is also aid, albeit of a more oblique variety.

The new pricing formula implies reduced rigidity in the application of world prices to intra-CEMA trade. It also suggests a heightened awareness on the part of the USSR of closer and broader economic ties with the non-communist world. However, it does not represent evidence of any fundamental reform in the intra-CEMA trading system. World prices are evidently being applied in more flexible fashion. But they are not being phased out as key determinants of CMEA trade prices, and—more important—there is no indication that the new formula is leading to the elimination of the distinction between hard and soft goods. (See Section V.) Closer East-West economic relations do not appear, therefore, to be producing any systematic effort to introduce realistic domestic prices and, with them, realistic exchange rates, in Eastern Europe and the Soviet Union. Such an effort is presumably a necessary condition of fundamental change in the intra-CEMA trade system.

#### V. INTRA-CEMA HARD CURRENCY TRADE

The 1975 price changes and subsequent occurrences implied that trade settled in hard currency or, what amount to the same thing, exchanges of goods at current and realistic world prices, would increase, accounting for a growing share of total intra-CEMA trade.

Such a development would have been logical, particularly as regards the trade of CEMA's most powerful member, the USSR. As already observed, even with the improvement in Moscow's terms of trade in 1975, the Soviet Union was still selling much of its exports of oil, and other raw materials, at what amounted to below world market prices, that is, on terms less favorable to itself than were available in non-communist markets. To at least partially offset this continuing subsidy to Eastern European countries, it would make sense for the USSR to increase trade at more realistic ratios of exchange for some portion of its trade.

There have been several indications that intra-CEMA hard currency trade may indeed be increasing. At the time the 1975 price changes were disclosed, it was announced that, in 1975, the USSR would deliver to Hungary 760,000 tons of crude oil above the 6 million tons of planned shipments, with the additional quantity to be paid for by Hungarian purchases in "third markets." The strong implication was that some 11 percent of Hungarian imports of crude oil from the USSR was to be paid for in hard currency. The purchase in third markets presumably referred to goods bought in the West for delivery to the USSR. If this were the case, the arrangement would have been substantively no different from a direct Hungarian hard currency payment to the Soviets which was used to import the desired goods from Western countries.

In mid-1976, a ten-year "above plan" trade agreement between Hungary and the USSR was announced. It called for exchanges of raw materials between the two countries, with the value of such trade in the first five years of the agreement estimated at about 8 percent of planned trade in 1976-80. The implication again was that this trade would take place at world prices.<sup>20</sup>

Unfortunately, aggregate data for CEMA as a whole that could establish the size of hard currency trade within CEMA recently and in the more distant past are lacking. What little comprehensive statistical evidence that is available does not support a conclusion of significantly expanded hard currency trade in the wake of the 1975 price revisions.

It should be made clear that some hard currency trade among CEMA members has always taken place. Writing in 1968, Ausch commented, ". . . certain 'hard commodities' are even now paid for in convertible currency." He then added, "This however, has nothing to do with the bilateral accounts led in clearing rubles."<sup>21</sup> In other words, hard currency trade is sealed off from the normal workings of the system and presumably is a small portion of total trade among communist countries. A Polish economist reported that in 1964-70, 10 to 25 percent of intra-CEMA trade was settled in hard currency.<sup>22</sup> The extremely broad range of this estimate implies considerable lack of information about such trade or lack of a clear or agreed upon definition of it or both.

Specific hard currency trade totals can be derived for only one country, Hungary. This can be done by subtracting figures the Hungarians publish for "ruble trade" from the Hungarian trade category labelled trade with socialist countries. The residual can be considered, or defined, as hard currency trade with socialist countries. We made such calculations for 1971-75, as shown in Table 2 below:

TABLE 2.—HUNGARIAN HARD CURRENCY TRADE WITH SOCIALIST COUNTRIES 1971-75<sup>1</sup>

[Millions of U.S. dollar]

Year:	Exports	As percentage Socialist exports	Imports	As percentage Socialist imports	Balance	Balance as percentage of total hard currency turnover
1971.....	\$59.4	3.5	\$105.3	5.5	-\$45.9	27.8
1972.....	49.1	2.2	84.6	4.1	-35.5	23.7
1973.....	203.3	6.9	133.3	5.5	70.0	20.8
1974.....	342.1	10.3	291.3	9.4	50.8	8.0
1975.....	398.7	9.4	273.8	5.9	124.9	18.6
1971-75.....	1,052.6	7.0	888.3	6.2	164.3	7.0

<sup>1</sup> See Appendix 2 for derivation of data in this table.

Source: "Statizkikai Havi Kozlemenek," various issues.

<sup>20</sup> Not all intra-CEMA hard currency trade need be "above Plan." According to Paul Marer, citing Carl H. McMillan, ". . . when an Eastern European country is committed under an East-West cooperation agreement to payment in convertible currency for royalties or parts and service, it will undoubtedly press for hard currency payment when the resulting products are exportable." (See Paul Marer, "Prospects for Integration in the Council for Mutual Economic Assistance (CEMA)," *International Organization*, Volume 30, Number 4, Autumn 1976, Footnote 21, p. 647.) However, given the tiny share of such exports in intra-CEMA trade at this point, the amount of hard currency involved is probably exceedingly small.

<sup>21</sup> Ausch, "Theory And Practice of CMEA Cooperation," p. 184.

<sup>22</sup> J. Rutkowski, "Polish-USSR Financial Relations and Multilateral Cooperation Among CMEA Countries," *Sprawy Miedzynarodowe*, November 1972. Cited in Mark Allen, "The Evolution of the International Bank for Economic Cooperation, 1964-1973," (unpublished paper, Washington, D.C., 1975).

The above figures suggest that some expansion of Hungarian intra-CEMA hard currency trade took place during the five year period. However, in 1975, there was a decline—slight for exports, steep for imports—in the share of Hungary's total socialist trade accounted for by hard currency transactions.<sup>23</sup> Furthermore, even at the 1974 peak, the ratio of hard currency trade to total trade was relatively low, about 10 percent.

One should be extremely wary, however, of generalizations drawn from the Hungarian data about overall intra-CEMA hard currency trade. To begin with, the findings in Table 2 may not be representative of the corresponding ratios for other CEMA countries (although there is no reason to assume that they are not). Secondly, the data may understate the actual amount of Hungarian hard currency trade, since some hard currency transactions that involve explicit hard currency expenditures are excluded from the residual because of the way in which the transactions are registered. For instance, Hungarian purchases in a "third market" of goods for delivery to the Soviet Union, though in fact a hard currency payment to the USSR, might be listed as either a Hungarian or a Soviet import from a Western country and not be included in "socialist trade." On the other hand, as a Western economist has pointed out, the data could overstate actual hard currency trade to the extent that they include transactions involving "re-exports of commodities acquired or disposed of in nonsocialist markets."<sup>24</sup>

A further source of uncertainty is the fact that what constitutes the residual in intra-CEMA trade is not known. Table 2, for example, may include only transactions in which hard currency balances held in financial institutions such as IBEC and Western banks were transferred between Hungary and other CEMA countries. It could, however, include transactions in which goods were exchanged at "hard currency prices," i.e., realistic, current world market prices, but in which no explicit transfers of funds took place. The utility of the reported data depends, therefore, not only on their accuracy but on whether one believes that the latter category should be defined as hard currency trade.

Despite these difficulties, the available evidence, what there is of it, does imply that hard currency trade is a relatively small portion of total intra-CEMA trade, or, at a minimum, it does not refute this hypothesis.

The lack of rapid growth in intra-CEMA hard currency trade indicates, we believe, that the intra-CEMA trading system is not undergoing fundamental change, in the direction of multilateral trade within CEMA and the convertibility of CEMA currencies with each other and with the currencies of noncommunist countries. In our view, hard currency trade would only lead to genuine reform if it rose to a very high proportion of intra-CEMA trade—with the distinction between hard and soft goods eliminated. However, erasure of this distinction would not be a sufficient condition for expanded intra-CEMA multilateralism and convertibility.

<sup>23</sup> Possibly, the introduction of more realistic price relationships in 1975 was responsible for the decline. This is of course a highly speculative explanation.

<sup>24</sup> Jozef M. P. Van Brabant, "Bilateralism and Structural Bilateralism in Intra-CEMA Trade" (Rotterdam, Rotterdam University Press, 1973), fn. 32, p. 278.

It should be made clear that we define hard currency trade to include not simply transactions involving explicit transmission of hard currency funds from one CEMA country to another but all transactions including barter-type or transferable ruble denominated transactions that are conducted at exchange ratios that truly reflect prevailing world market price relationships. Such transactions have, or could have, the effect of linking Eastern European economies more closely with the West. For example, if one CEMA country trades oil to another CEMA country in return for coal at realistic prices, the oil exporter need not physically import the coal. If it so desires, it could order the coal shipped to a Western buyer for hard currency, to be used as the oil exporter chooses.

Such transactions in isolation do not, however, alter the bilateral character of intra-CEMA trade. Payments between CEMA partners are, in effect, still flowing in bilateral channels. But if all or most intra-CEMA transactions were conducted on the basis of current, world market prices, then the distinction between intra-CEMA trade and trade of CEMA countries with the rest of the world would be significantly blurred. There would be no terms of trade difference between intra-CEMA, and CEMA countries-Western trade, and intra-CEMA trade thus would cease to be of economic benefit to those CEMA countries that now enjoy a relative terms of trade advantage.

It is therefore possible that trading at current world prices within, as well as outside of, CEMA would stimulate a marked increase in intra-CEMA multilateralism. The disincentive to hold transferable ruble balances growing out of transactions with one country for use in other countries would be reduced if the distinction between hard and soft goods ended. A consequence of this, particularly for Eastern Europe, where trade accounts for a substantial proportion of economic activity within CEMA, could be the creation of considerable pressure to allow domestic prices to more accurately reflect the interplay of production cost and demand factors, in order to facilitate more rational decisions on what to trade and in what amounts.<sup>25</sup> Realistic domestic prices in turn could clear the way for realistic exchange rates and convertibility within CEMA and with the rest of the world.

None of this need happen, however, just because CEMA trade prices accurately reflected world prices. Bilateralism might still persist because of the reduction in uncertainty, discussed in Section II above, that it provides to central planners. The commodity inconvertibility that accompanies bilateralism would therefore remain as a disincentive to accumulating TR balances. Furthermore, even with trade conducted at current world prices, it would remain feasible (though, of course, still economically inefficient) to maintain a system of disequilibrium domestic prices, with the attendant separation of trade prices from domestic prices, meaningless official commercial exchange rates, and infeasibility of convertibility. Bilateral barter trade could continue to predominate within CEMA, and trade with the West could continue to be conducted exclusively, with Western currencies, with no role for the currencies of the CEMA countries.

In any event, trade within CEMA with all or most transactions occurring at genuine world market prices—that is, with the distinc-

<sup>25</sup> Please note the assumption stated above that trade within CEMA, even with domestic prices determined by market forces, would generally be conducted at world prices because of the small role CEMA countries play in world trade as a whole.

tion between hard and soft goods obliterated—seems most unlikely in the foreseeable future. This would be true even if the theoretical and technical problems involved in pricing differentiated goods (such as machinery) could be solved, for example, by introducing suitable discounts to allow for quality differences between Eastern items and their Western counterparts. One reason is that many CEMA countries would find the termination of the distinction painful. Even when world price relationships have remained relatively stable, CEMA trade price relationships have been distorted in terms of world prices, primarily because of the “overpricing” of manufactured goods noted earlier in this paper. Countries that are mainly raw materials importers and manufactured goods exporters would thus lose what amounts to the subsidy they now enjoy in intra-CEMA trade.

To some extent, this subsidy may be less than it was formerly, but it appears to remain substantial. The Soviet Union, for example, has reduced the proportion of fuels and raw materials in its exports to Eastern Europe from 58 percent in 1965 to 55 percent in 1970 to 49 percent in 1974. (In 1975, the share rose to 61 percent, but the change was due in large measure to the price rises in 1975 and therefore must be discounted.) The share of finished manufactures in Soviet imports from Eastern Europe, on the other hand, was actually higher in 1974 than in 1965—67 vs. 64 percent. (The proportion in 1975 was 65 percent.) The ratio of Soviet exports of fuels and raw materials to Eastern Europe to Soviet imports of these items from Eastern Europe remained stable from 1970 to 1974 (4.62 in 1970, 4.54 in 1974). This in fact represented an increase from the 3.64 ratio in 1965. The ratio of Soviet exports to imports of finished manufactures trended upward from the mid-1960's, from .27 in 1965 to .45 in 1974. The rise in 1974 was particularly sharp, from .39 in 1973. The ratio fell back in 1975, however, to .39. None of these changes suggests any alteration of the Soviets' basic role as a supplier of raw materials to, and buyer of finished manufactures from, Eastern Europe.<sup>26</sup>

It is worth noting, incidentally, that greater balance of exports and imports within different categories of goods would not mean that exchange ratios reflected realistic prices or that there had been a move away from bilateralism. It would represent, rather, a shift toward conducting intra-CEMA trade on all separate soft goods and hard goods tracks within all continuing bilateral framework.

Sweeping introduction of realistic price ratios would damage the standard of living of much of Eastern Europe, where trade plays a far larger role in the economy than in the USSR, by pushing the terms of trade to the disadvantage of raw-material poor countries. The damage could be mitigated or delayed by the extension of credits through CEMA institutions to those CEMA countries that would suffer from the change in price relationships. However, with the distinction between hard and soft goods gone, rising intra-CEMA debt would be the equivalent of hard currency debt for the affected countries. Hard currency debt has already risen to very high levels in

<sup>26</sup> The above figures were computed from data in Paul Marer, “Prospects for Integration in the Council for Mutual Economic Assistance (CMEA),” Table I, p. 638 and (for the 1975 figures) from *Vneshnyaya Torgovlya SSSR v 1976 g.*

Eastern Europe, and debt servicing threatens to become a very serious problem.<sup>27</sup>

Opposition to across-the-board introduction of realistic world prices into intra-CEMA trade might, however, be based less on the threat of economic hardship than on more directly political considerations. As noted above, such a development would weaken CEMA's position as a distinct economic entity, something that might well be unacceptable to some CEMA members, notably the USSR. Furthermore, the possibility that it could stimulate greater economic efficiency and decentralization in Eastern Europe would pose a threat to communist party direction of economic policy, which would severely inhibit movement toward the comprehensive application of realistic world prices. Many political leaders in CEMA countries—again, particularly those in the USSR—would view the accompanying diminution of centralized control over economic affairs not only as ideologically offensive but, more to the point, as a drastic threat to their power.

### APPENDIX I

#### TERMS-OF-TRADE EFFECTS OF CHOOSING DIFFERENT TIME INTERVALS AS WORLD PRICE REFERENCE PERIODS

Table 3 below indicates the impact on the USSR's "terms of trade" vis-a-vis Eastern Europe of switching to 1970-74 and 1972-74, from 1965-69, averages of "world prices" as the reference interval for intra-CEMA trade prices.

TABLE 3.—TERMS-OF-TRADE EFFECT ON SOVIET UNION VIS-A-VIS EASTERN EUROPE OF CHANGING WORLD-PRICE REFERENCE PERIOD  
[1965-69=100]

<sup>1</sup> Sum of column.

Note: Terms of trade: 1970-74: 100 (160/141)=113; 1972-74: 100 (189/157)=120.

Sources: Vneshnyaya Torgovlya SSSR v 1975 g. U.N. Monthly Bulletin of Statistics, March 1973, p. xv-xvi; March 1976, p. xx-xxi; and December 1976, p. xxiv-xxvi.

<sup>27</sup> Eastern European countries already shun hard currency debt within CEMA. Since 1973, CEMA members evidently have been required to pay off 10 percent of the amount of their trade deficits within CEMA above some specified level in hard currency. The effect has apparently been to intensify the striving among potential debtors to achieve bilateral balance in order to avoid hard currency outlays. Even the most limited convertibility within CEMA evidently has a trade-shrinking instead of a trade-expanding impact. See Lawrence J. Brainard, "The CEMA Financial System and Integration," (Unpublished paper delivered at Conference on Integration in Eastern Europe and East-West Trade, Indiana University, Bloomington, Indiana, October 31, 1976).

The above results were derived as follows: Annual UN index numbers of world export prices for various commodity categories were averaged to yield a single value for each category for each of the three periods.<sup>28</sup> These values were then converted to index numbers with 1965-69 as the base period (equal to 100), by computing the percentage change from 1965-69 to 1970-74 and 1972-74. The resulting index number for each category was then weighted by the value of Soviet exports and imports in 1974 to compile indices for both exports and imports as a whole. The export indices were then divided by the corresponding import indices to yield the net barter terms of trade.

The terms of trade changes when the fuels component is excluded were computed as follows:

$$\begin{aligned} \text{Export index 1970-74} &= (160-48)/100(1-.1973) = 140. \\ \text{Export index 1972-74} &= (189-64)/100(1-.1973) = 156. \\ \text{Import index 1970-74} &= (141-6)/100(1-.0241) = 138. \\ \text{Import index 1972-74} &= (157-8)/100(1-.0241) = 153. \\ \text{Terms of Trade: 1970-74: } &100(140/138) = 101. \\ &1970-72: 100-72: 100(156/153) = 102. \end{aligned}$$

It should be stressed that the indices above are intended only to suggest the importance that oil price changes must have had in influencing the Soviet decision to switch from 1965-69 to a new reference period. The UN indices were used because they are indicative of movements in world prices, not because there is any evidence that CEMA countries actually rely on them in negotiating trade prices. The highly aggregated character of the commodity groups to which the UN price indices apply is another reason why the above measures of changes in Soviet-Eastern European terms of trade must be considered very rough. Fuels, for example, include components besides oil. The aggregation problem is most serious with respect to the manufactures group, which consists of an extremely heterogeneous collection of manufactures and semi-manufactures corresponding to SITC Classification groups 5 through 8. (These, in turn, are roughly equivalent to Soviet Trade Classification groups 1, 3, 4, 9, and parts of 2.)

We also constructed similar terms of trade indices for later periods, for which UN price indices for individual commodities were available. We were thus able to compile indices based on far more disaggregated components, with separate indices for such commodities or commodity groups as oil, coal, lumber, cotton, wheat, wine, iron ore, aluminum, copper, zinc, and lead. Indices for the same periods using the more aggregated components shown in Table 3 were also compiled. In general, terms of trade indices using the more aggregated components did not differ much from the counterpart indices based on more disaggregated data. However, we were unable to disaggregate the manufactures price indices. Therefore, the reliability of the terms of trade indices based on the more disaggregated components may not be significantly greater.

The additional indices were intended to gauge the effect on the terms of trade of using current world prices in 1975 and 1976 instead of lagged averages, as was actually done. (For 1976, UN price indices were available for the first three quarters only.) Calculations were made including oil and then excluding it. The

<sup>28</sup> 1970 was the base year for all annual index values except 1965 and 1966, for which 1963 was the base year. To compute the 1965-69 average, the 1965 and 1966 values were converted to the 1970 base by computing percentage changes from 1965 and 1966 to 1967 for the values using 1963 as the base year and then applying these percentage changes to the 1967 value using 1970 as the base year.

results, which again underscore the importance of oil, are summarized in Table 4 below.

TABLE 4.—TERM-OF-TRADE EFFECT ON U.S.S.R. VIS-A-VIS EASTERN EUROPE OF USING CURRENT INSTEAD OF LAGGED WORLD MARKET PRICES  
[1970-74 or 1972-74 or 1971-75=100]

Period and type of index	Term of trade

## APPENDIX 2

### DERIVATION OF DATA ON HUNGARIAN HARD CURRENCY TRADE WITH SOCIALIST COUNTRIES

In 1976, Hungary began to furnish breakdowns of its foreign trade between socialist and non-socialist countries and between ruble and non-ruble accounts. Estimates of hard currency trade with socialist countries from 1971-75 were obtained by subtracting total ruble accounts, both for imports and exports, from socialist country totals, and converting the difference, expressed in devisa forints, into dollars at the official rates of exchange that prevailed during each year. These were: 1971—\$1=11.74 dft.; 1972—10.81 dft.; 1973—9.5 dft.; 1974—9.15 dft.; 1975—8.6 dft. Although Yugoslavia is listed as a socialist country, its imports and exports were excluded from the socialist country total because it was felt that some, if not all, of Hungarian-Yugoslav bilateral imbalances from 1971-75 were settled in convertible currency.

The data thus derived and presented in Table 2, should be qualified to take account of Brainard's observation that Hungarian imports are listed c.i.f. and exports f.o.b. He notes that ruble statistics for Hungarian imports in the CEMA yearbook are expressed in contract prices and so provide a surrogate computation for f.o.b. prices. The results obtained naturally reduce estimated hard currency imports below those given in Table 2, reducing the deficits in 1971-72 and enlarging surpluses in 1973-75.<sup>29</sup> The discrepancies, however, are not large, and do not alter fundamentally the conclusions arrived at in this paper.

<sup>29</sup> See Brainard, "The CEMA Financial System and Integration."

## I. INTRODUCTION

This paper attempts to provide an overall, perspective appraisal of the Council of Mutual Economic Assistance (CEMA) in the spring of 1977, nearly 30 years after it was organized in Moscow as a Stalinist riposte to the Marshall Plan.

Since that time the economies of the Soviet Union and the countries of Eastern Europe have grown and expanded and become more complex, as has the CEMA organization itself. Two principles, however, which were valid in 1949 remain unchanged today. They are (1) that

\*It should be understood that the views expressed in this paper are those of the author and do not necessarily represent the position of the Bureau of East-West Trade, Department of Commerce, JEC, or the U.S. Government.

CEMA is composed of a group of relatively small countries and a superpower, the USSR, and (2) that the ultimate, long-term objective of the organization is the achievement of a highly organized, integrated economic bloc—even though there appears never to have been full agreement on just how and when this integration will be accomplished and despite the fact that the principle of sovereignty and independence of member states is a cardinal feature of the CEMA statutes. Consequently, it is important to keep in mind that the word “CEMA” in many cases is equivalent to the word “Soviet” because of the strong identity of interests and objectives.

In light of the above it is interesting to try to evaluate how much success has been achieved in recent years in accomplishing CEMA goals. What gains have been made, especially following the announcement in mid-1971 of the extensive and ambitious plans for a twenty-year Complex Integration Program (1970–1990)? And what has been the impact of the worldwide economic upheavals caused by the energy crises of 1973–1974 and the subsequent shock-waves of acute inflation in the Industrial West?

It is important, of course, to estimate these gains, as well as any difficulties, as they are viewed from Moscow and not from London, Washington or Bonn. CEMA is not an “open organization.” A large volume of important economic data on member countries and their relations within CEMA—ranging from such items as gold and hard currency reserves to details of multilateral agreements—is unpublished and impossible to obtain. Consequently, it is only possible to delineate some of the most important developments on the basis of the sparse material occasionally published in the Soviet and East European press or in official CEMA publications. This material nevertheless presents a picture of a much more complex and more active organization today than in the 1950’s and 1960’s, and one that is continuing to move slowly but steadily forward.

## II. ECONOMIC GAINS: TIGHTER INTEGRATION THROUGH EXPANDED INFRASTRUCTURE AND AN INCREASED EAST EUROPEAN DEPENDENCE

Over the past ten years, and especially since 1971, a series of developments have taken place which have resulted in a stronger CEMA organization and a much more extensive infrastructure for integration activity. Some of these developments have received very little or only marginal attention in the West and some have been noted only in Western academic or business circles concerned with East European and Soviet economic matters. Because they are often very technical and obscure, their role in the organization goes unnoticed. The following are some of the more important.

### (A) *Deterioration in East European Terms of Trade With the USSR*

Much has already been written about the unexpected and sudden CEMA Executive Committee decision early in 1975 to increase intra-CEMA foreign trade prices, despite the fact that the next scheduled intra-CEMA price revision was not due until 1976. The actual and widely publicized reason (in the West) was Soviet realization that the violent increases in world energy and raw material prices triggered by the energy crisis of 1973/74 were causing the USSR to lose too much in

exporting oil, natural gas and raw materials to East European CEMA countries at bargain-basement 1966 rates. Prices had to be brought into line and, accordingly, the prices of a large number of goods—raw materials, manufactures, agricultural products as well as energy—were raised substantially.

But the big jump was in oil, for which five of the six East European CEMA members (Romania excluded) were almost entirely dependent on the USSR. The price of crude oil in intra-CEMA trade moved upward by about 130 percent, although this resulted in a price which was still quite a bit less than East European countries must pay in Western markets. Nevertheless, since oil, along with natural gas and industrial raw materials, played a pivotal role in Soviet exports to Eastern Europe, the price increases for these commodities inevitably resulted in an immediate deterioration—estimated at about ten percent—in the terms of trade of the six East European CEMA members with the USSR.<sup>1</sup> In simple terms, the six East European CEMA countries suddenly found themselves having to increase their exports to the Soviet Union in order to maintain the same level of imports from the Soviet Union that they had been receiving in recent years.

All available evidence indicates that this deterioration in terms of trade has continued. The prices which the smaller CEMA countries are paying for Soviet raw materials and products are still generally less than they would be paying to non-communist suppliers, and they also have the considerable advantage of not having to pay in hard currency, but they must nevertheless pay *more* in exports of machinery, consumer goods, food products and services than they were paying before the 1973 energy crisis.

The actual nuts-and-bolts impact of this terms of trade loss for small East European countries is not immediately visible. Obviously, it means increased strains on their economies, some decline in standards of living, a reduced rate of economic growth. Here and there, however, some precise information, some hard statistics have become available.

Thus, in December 1976 a special symposium on the GDR economy conducted by a West German research institute (*Deutsches Institut für Wirtschaftsforschung*, Berlin West) attributed the current slowdown in the GDR's economic growth rate primarily to the deterioration in its terms of trade with the USSR. The symposium found that the GDR had three ways of meeting this situation—increasing debt, restricting imports and raising exports. All three had been done, along with a restructuring of the economy at the expense of the domestic market. In 1975 the GDR had experienced its largest deficit ever—VM 4.2 billion—due mainly to increased Soviet energy and raw material prices. It was also found that efforts to increase exports to the USSR had reduced available goods for export to Western hard currency markets.

Another insight into the impact of the higher CEMA foreign trade prices on the GDR appears in some official GDR statistics for economic performance in 1976 which were released in January 1977.

<sup>1</sup> For a thorough and expert discussion of this subject see "Developments in Soviet-Eastern European Terms of Trade, 1971-75" by Martin J. Kohn, published in "Soviet Economy in a New Perspective," Joint Economic Committee, Congress of the United States, Oct. 14, 1976.

They show that GDR national income grew by only 3.7 percent in 1976, the lowest rate since 1963. The official explanation of the GDR statistical administration was "difficulties in agriculture and in foreign trade." And a brief reference to foreign trade performance included the comment that GDR foreign trade commitments to the USSR and other CEMA countries had been met and that "additional foreign trade expenditures by the GDR were necessitated by changes in CEMA prices." It was also stated that inflation in the West had made the GDR's imports from that area more expensive.

It is perhaps significant that, in contrast to previous years, official 1975 GDR foreign trade statistics were lumped together—exports and imports—into an overall "turnover" figure which makes precise analysis more difficult. Whether this was done deliberately in order to conceal the difficulties which the GDR may be having in its trade with the USSR can only be conjectured.

*(B) East European Participation in Soviet Raw Material and Energy Development Projects*

The large-scale, "multilateral" CEMA development project has become an increasingly familiar phenomenon in official CEMA communiqués and reports over the past several years. In simplest terms it involves extensive East European investment and assistance in the extraction, processing and transport of Soviet raw material and energy resources. This is natural wealth which makes up part of the impressive figures on estimated Soviet reserves of energy and raw materials but it is still in the ground in remote areas of the country. Each East European participant agrees to provide specified items of capital equipment, e.g. railway cars, tractors, steel rails, bulldozers, prefabricated housing, and will receive repayment in the product of the project over a specified period—usually ten to twenty years. East European contributions may also include skilled labor and technology. The price of raw material or energy received is fixed at a figure below the world market price.

The multilateral projects are massive contracts which are often dramatic in their scope and pioneering ambience. As such they provide good subjects for publicity about fraternal socialist cooperation, the advantages which accrue to the East European countries from membership in CEMA and, by implication, from the benevolent assistance of one of the richest countries in the world, the USSR.

The outstanding multilateral project to date is Orenburg. The Orenburg natural gas pipeline is now under construction over a more than 1200 mile route which extends from the area of gas condensate deposits near Orenburg in the southern Urals to the Czechoslovak-Soviet frontier near Uzhgorod in the Carpatho-Ukraine. When completed during the last quarter of 1978 it will be the largest natural gas pipeline in the world. The Orenburg participants are the five CEMA East European countries and the USSR, with Poland, the GDR, Czechoslovakia, Bulgaria and Hungary each being responsible for a specific sector of the pipeline and the Romanians responsible for the import from Western Europe of one or more gas scrubbing plants being assembled at Orenburg for the conversion of gas con-

densate into natural gas.<sup>2</sup> The total value of the project is about six billion rubles (approximately eight billion US dollars) and according to current plans the East European participants will eventually receive 15.5 billion cubic meters of natural gas each year for much less than the world market price. This may cover as much as one-fifth of CEMA East European natural gas requirements in the year 1980.

The number of CEMA multilateral development projects has been increasing steadily and there have been reports that as many as 15 or 20 are planned. In each case the project is first presented at one of the annual CEMA Council meetings where it is approved by those countries wishing to participate. A series of bilateral agreements are then negotiated between each participating country and the USSR. These may take a year or more to conclude and specify just what equipment, technology, and manpower each participant will provide and how much raw material or energy it will receive in return. Although the value of investments and the prices of the raw material or energy product are not published, it appears that they are based on special formulae which are closely related to intra-CEMA foreign trade pricing and, accordingly, make use of world market price indexes.

The following summarizes the major CEMA multilateral projects which have been announced to date. Except where noted the participants, along with the USSR, are the six East European CEMA members.

Name and location	Product	Remarks
Orenburg pipeline (from Orenburg in southern Urals to Czechoslovakia-Soviet frontier near Uzhgorod).	Natural gas; also sulfur as byproduct from conversion of gas condensate.	EE participants to receive 15,500,000,000 m <sup>3</sup> of gas per year starting last quarter of 1978. Additional gas to be exported to Western Europe by U.S.S.R. and some to be used by U.S.S.R. in areas along pipeline route.
Ust Ilmsk (on Angara River north of Bratsk in eastern Siberia).	Cellulose.....	Czechoslovakia not participating. In addition to EE/CEMA investment, important role being played by French and Swiss firms.
Kiyembaev (southern Urals).....	Asbestos.....	East European participants to receive between 40,000-50,000 tons of asbestos per year. Exports may cover about 1/3 of EE requirements in 1980.
Kursk (rich iron ore deposits covering many square miles near city of Kursk about 300 mi south of Moscow in R.S.F.S.R.).	Iron ore, iron and steel pellets, steel.	Romania reportedly not a participant; also reportedly delayed until 11th 5-yr plan beginning 1980. FRG firms now building 1 sector near village of Starly Oskol' which will be 1 of the largest metallurgical complexes in world.
Norilsk (northwestern Siberia near Yenisei River).	Copper and nickel.....	Financed by CEMA International Investment Bank credit but few details available.
Vinnitsa-Albertyrsha powerline (from central Ukraine to Hungary).	Electric power.....	A 750-kV line which will increase transfer of power from European part of U.S.S.R. to Eastern Europe.
Cuba (exact location not known).....	Nickel ore.....	First multilateral project not completely or partially on Soviet territory. Announced in 1976. Few details available.

Even a superficial analysis of these multilateral contracts indicates that they increase East European dependence on the Soviet Union both as a source of raw material and energy supply and as a market for East European equipment.

The source dependence involves a long-term, "locked in" regular acquisition of essential raw materials and energy at *very* favorable prices. Thus, the cellulose shipped to Hungary from Ust Ilmsk will

<sup>2</sup> The Romanians have purchased at least one plant from France for conversion of gas condensate into natural gas. A number of articles in East European newspapers have indicated that Bulgaria, Hungary and Czechoslovakia have been unable to fully meet the manpower requirements for construction of their sectors of the pipeline. Consequently, the USSR is providing the necessary skilled labor with wages being paid by the respective East European countries. Each country is also responsible for construction of the necessary compressor stations to be erected in its sector, most of which are reportedly being imported from the West.

arrive regularly through the year 1990 at prices well below those which Hungary might have to pay to nearby Austria or to Scandinavia. Furthermore, payment will be in Transferable Rubles or through some other clearing account mechanism, whereas Austrian or Scandinavian sellers would demand hard currency. After 1990, when the USSR will presumably have paid back the Hungarians for their investments in Ust Ilimsk, the Hungarians will be required to "renegotiate" their contracts for Ust Ilimsk cellulose. Presumably this will result in payment of some higher prices but prices still below those on the world market.

The market dependence, although perhaps less extensive, can nevertheless be significant. For each project the EE participant is required to divert an important section of its industry to the production of equipment for its contribution. These diversions presumably extend over several years. And they may also, as in the case of Orenburg, require substantial allocations of skilled labor and managerial personnel.

Finally, the East European contribution can also involve diversions from hard currency reserves for purchase of components which must be imported from the West. One outstanding example has been the Romanian purchase of gas condensate processing plants from France for use at Orenburg. In another instance, Hungary has been buying American bulldozers for use in the construction of its section of the Orenburg pipeline.

The net result then, is a "compulsory", predetermined diversion of trade eastward which must inevitably reduce by a fixed percentage the quantity of resources which would normally be available for East European trade with the West. And this diversion is a long-term, inelastic affair tending toward permanency—a definite gain for the CEMA objective of integration and interdependence.

(C) *The CEMA Banks: Sophisticated Financial Support for Trade and Development*

As recently as five or six years ago mention of the two CEMA Banks—the International Bank for Economic Cooperation (IBEC) and the International Investment Bank (IIB) would have meant very little in Western financial circles.

The IBEC was established in 1964, primarily to facilitate multi-lateral trade among the CEMA countries through the use of the Transferable Ruble (TR), a widely publicized device which is a unit of account for clearing operations and not a new form of currency. The IIB was established six years later, in 1970. Its announced purpose was to provide long-term development loans in both Transferable Rubles and hard currency for capital projects which would benefit two or more CEMA countries.

In the first few years after they were established both banks attracted relatively little attention, especially since their hard-currency operations were limited. Now, in the mid-1970's, the situation is much changed. Both banks are increasingly active in Western hard currency markets, both are well known in Western international banking circles and they have been increasingly important in the promotion of intra-CEMA trade and the development of CEMA infrastructure.

The IBEC's main emphasis has been on intra-CEMA trade which it has facilitated through the use of the Transferable Ruble as a clearing mechanism. Despite the theoretical possibilities for the use of the TR in multilateral clearing, almost all intra-CEMA trade handled by IBEC in recent years has been bilateral.

A much more interesting development, however, has been IBEC's strong upward movement in hard currency operations. From its inception IBEC has always assisted CEMA countries in East-West trade transactions, and has extended short-term credits in both TR's and hard currency. Over the past five years the annual volume of IBEC hard currency operations has increased very sharply, rising from 28 percent of total operations in 1971 to 40 percent of all operations in 1975. The reasons for this have been the strong increase in Soviet and CEMA East European trade with the Industrial West and also what is believed to be a significant increase in intra-CEMA hard currency trade. The latter includes East European purchases at world market prices of certain quantities of Soviet energy and raw materials in excess of the normal allocations which they receive for Transferable Rubles through regular bilateral trade agreements. And it also includes special purchases of manufactures and raw materials arranged between CEMA East European countries. The exact scope and details of this interesting aspect of intra-CEMA trade are almost impossible to determine, but some experts believe that it is growing at a much faster rate than regular trade carried on through clearing and bilateral agreements.<sup>3</sup>

Another aspect of IBEC's growing involvement in the world of hard currency has been its increased activity in short and medium-term Eurodollar borrowing for CEMA countries, and its participation, along with some of the major Western banks, in syndicate Eurodollar loans to developing countries.

The CEMA International Investment Bank has become a significant, active force both for development of intra-CEMA infrastructure and in expansion of CEMA trade and financial relations with the Industrial West. Since its commencement of operations early in 1971 the IIB has extended approximately 50 credits for industrial development projects which meet the criteria of promotion of the "international socialist division of labor" by benefiting two or more CEMA countries. These have ranged from a wool washing plant in Mongolia and a citrus fruit canning plant in Cuba to modernization of the Hungarian railway system and the huge Orenburg natural gas project.

As with IBEC, the IIB involvement in hard currency operations has increased dramatically. The Bank's capitalization now includes a sector of 30 percent in convertible currencies and gold (capitalization on Jan. 1, 1976 was about TR 1.1 billion or \$1.4 billion) and since 1973 it has been very active in Western Eurodollar markets. Eurodollar loans for purchase of Western-made pipe and other equipment for Orenburg, obtained by IIB from Western banking syndicates, have totalled over one billion dollars and there are indications that additional borrowing will take place in 1977.

<sup>3</sup> For further discussion of the expanding role of hard currency in IBEC and IIB operations, see David Lascelles, *Financial Times*, London, "COMECON's Potential," a paper presented at the NATO Colloquium on COMECON, Brussels, March 1977. See also, "Operation and Importance of the IBEC and the IIB, and the COMECON Quest for Credits," paper prepared by Dr. H-D. Jacobsen, Stiftung Wissenschaft und Politik, Ebenhausen, also presented at the NATO Colloquium.

In keeping with the objectives of CEMA integration, therefore, the two CEMA banks appear to be playing a useful and effective role. In addition to providing centralized mechanisms for such operations as trade clearing and project financing, they are becoming valuable intermediary agencies for rounding up Western financial support—through Eurodollar and other borrowing—for CEMA multilateral projects. In this latter operation they represent the entire CEMA bloc in dealing with Western financial institutions and can—presumably—achieve more than individual East European national banks or even the Soviet Union's *Vneshtorgbank* might be able to accomplish if it were acting alone.

#### (D) *Centralized Plan Coordination*

One of the main aims of the Complex Program is complete coordination of all the national economic plans of all member countries. Work on this grandiose and tremendously involved scheme was, however, not begun until the year before the 1976–1980 five-year plan period. In essence, what is required is the coordination of each of the plans of each of the nine member countries with the opposite-number plans of all the others. Thus, the GDR plan for heavy machine building would be coordinated with the Bulgarian plan for heavy machine building, the Soviet plan for heavy machine building, the Polish plan for heavy machine building etc.<sup>4</sup>

Despite numerous articles and exhortations in the Soviet press, it appears that the plan coordination program still has some way to go. There seems to have been some initial progress in coordination of foreign trade plans. During 1976 announcements of plan coordination for five-year foreign trade plans by different CEMA countries appeared in the Soviet press and there were reports of numerous meetings of foreign trade plan coordination groups in different capitals.

The integrational impact of plan coordination is obvious. At minimum it limits the flexibility which individual CEMA East European countries can have for trade with countries outside of the CEMA bloc. And there have already been some indications of this in the announcement of long-term commitments for exports to other CEMA countries. In Hungary, for example, the reported conclusion of several long-term contracts for the export of vegetables, fruits, and other foodstuffs to the USSR could reduce Hungary's options for the export of certain portions of its agricultural output to Western countries in future years.

#### (E) *The CEMA "International Economic Organizations": Incipient Supranationality?*

Since 1971 there has been a significant increase in a new form of specialized intra-CEMA organization. These are generally referred to as "international economic organizations". They are regularly and understandably confused with the approximately 25 permanent

<sup>4</sup>The potentially very powerful CEMA Planning Committee (Committee on Cooperation in Planning Activities) consists of the Planning Ministers of all member countries led by USSR GOSPLAN Chairman and Vice Premier N. K. Baybakov. At the 27th Session of the CEMA Council in June 1973 it was directed to begin work on increasing intra-CEMA cooperation. At the 29th Council meeting in 1975 the committee submitted a draft proposal for a coordinated, CEMA-wide plan. The full details of this document have not yet been published.

Standing Commissions which cover specific economic sectors, such as geology and coal industry, and date back to the early 1950's, and the CEMA Intergovernmental Organizations, such as "Interkhim" (chemical industry) and "Intermetal" (steel production, special types of steel).

The "international economic organizations" (IEO's) were officially launched at the 61st meeting of the CEMA Executive Committee on January 23, 1973. Their objective is to establish specialized cooperation and coordination in industrial production at the enterprise level and across national frontiers. In some respects the IEO's might very roughly be described as socialist multi-national corporations. Thus, Interelektro, established in 1974, is concerned with the coordination of production of electric motors and various types of electric equipment, and membership apparently includes plants in all six East European CEMA states. One of Interelektro's earliest and most publicized accomplishments has been assistance in the organization of an electric-motor and equipment factory at Novovolynsk in the Ukraine, not far from the Soviet-Polish frontier.<sup>5</sup> The Novovolynsk plant is unusual because it is a three-way cooperative effort involving Soviet, Polish and GDR investment, equipment and personnel. In essence, it carries out co-production, three countries producing one standard electric motor.

Interelektro is chaired by a Deputy Minister of the Soviet Ministry for Production of Electric Equipment, has its main offices in the USSR, and its official, long-term objective is "the working out of common technical requirements for production of equipment so that CEMA countries will no longer be producing a number of different models" (of what is apparently the same item).<sup>6</sup>

Although information on the IEO's is limited, it is known that headquarters may be in various member countries, that the Chairman or Director is a national of the host country, and that their financing is through the currency of the host country and in Transferable Rubles. Over the past four or five years it appears that the following IEO's have been established: (except where noted all East European members participate):

Organization	Headquarters	Production specialty
Interelektro	Moscow	Electric motors, electrical equipment.
Intertekstil'mash	do.	Textile machinery.
Interatominstrument	Warsaw	Nuclear technical equipment.
Interchimvolokno	Bucharest	Artificial fibers.
Interatomenergo	Moscow	Nuclear powerplants.
Assofoto <sup>1</sup>	do.	Photographic industry (films, chemicals.) <sup>2</sup>
Mongolsovtvetmet <sup>3</sup>	Ulan Bator	Copper and molybdenum ores. <sup>4</sup>
Domochin <sup>1</sup>	Moscow	Household chemical products (detergents).

<sup>1</sup> Only U.S.S.R. and German Democratic Republic participating.

<sup>2</sup> Assofoto appears to be a major producer of photographic film and magnetic recording tape involving genuine coproduction by the German Democratic Republic and the U.S.S.R. according to articles in the Soviet press. There are production facilities in both the German Democratic Republic and the Soviet Union, management consists of nationals from both countries and there is also joint investment.

<sup>3</sup> Only U.S.S.R. and Mongolia participating.

<sup>4</sup> Mongolsovtvetmet is mentioned in an article by Mongolian Deputy Premier Damdinjabin Maydar published in Pravda, Sept. 17, 1975. See also "Narodnoye Khozyaystvo MNR 1973," Ulan Bator 1974.

<sup>5</sup> *Sotsialisticheskaya Industriya*, Moscow, May 20, 1974, and subsequent articles in the same newspaper.

<sup>6</sup> *Ibid.*

Information on the activities of these organizations is limited and spotty. It is known that, variously, they are concerned with research, exchange of information, coordination of production, planning, management, foreign trade, marketing and sales. How successful they have been so far, how efficient they are or may be, remains to be seen. Nevertheless, they constitute an interesting structural framework for movement toward supranationality at a technical and production instead of governmental level. The plans of Interelektro, for example, to promote common, bloc-wide manufacture of the same type of electric motor, and also its work on joint-production by three neighboring countries could, presumably, be as effective as orders handed down from a higher, supranational body.

(F) *The Protocol on "Technical Standardization"*

Closely linked with the cross-frontier, intra-CEMA cooperation and uniformity in industrial production which the "international economic organizations" seek to promote is the massive CEMA technical standardization program. A CEMA Institute for Standardization has been in existence since 1950 but appears to have been more latent than active until the early 1970's and the inauguration of the Complex Program.

In essence the current CEMA Standardization Program is just what its name implies: the establishment of common scientific, technical and industrial standards for industry, science, agriculture and other economic sectors throughout all nine member countries. Probably patterned after GOSSTANDART, the Soviet equivalent of the U.S. Bureau of Standards, the standardization program moved into high gear at the 28th CEMA Council Meeting in Sofia in 1974. At that time a standardization protocol was presented, approved and signed by all member countries except Romania (which finally signed about one year later). In essence, the Protocol called for compulsory adherence by member countries to CEMA technical standards as they were announced at regular intervals by the CEMA Standardization Commission. This meant that the signatory countries must instruct their industries, design centers, scientific laboratories etc. to adhere to a CEMA standard within a certain time period after announcement was received from Moscow that the CEMA standard for the particular item had been fixed.

It appears that the CEMA Standardization Commission examines and approves many hundred of standards each year. The total for the year 1975 was more than 2300 according to one Soviet article.<sup>7</sup> Official procedure requires that the standards selected incorporate the best production of a particular item to be found in all nine countries. Thus, if a Czechoslovak turret lathe is found to be best in design and efficiency, then it is accepted as best and within a fixed period (not-stated) turret lathes produced in all other CEMA countries, including the USSR, must meet the standards of the Czech machine. Furthermore, the CEMA standard becomes law in each country, another move toward lower-level supranationality.

<sup>7</sup> Pravda, Jan. 21, 1975. The article, by N. Boytsov, Chairman of the CEMA Standardization Commission, notes that the GDR and Bulgaria are leaders in meeting CEMA standardization targets.

(G) *The Numerous and Often Unreported Intra-CEMA Bilateral Agreements*

Although the large CEMA multilateral agreements for raw material and energy development discussed in (B) above have received considerable publicity, there has been relatively little on the smaller intra-CEMA agreements which involve two or three countries. These include a considerable network of organizations and associations—the IEO's mentioned in (E) above, other organizations called “joint enterprises” and “international economic unions,” and the specialized inter-governmental organizations. All together they make up a complex labyrinth.

One of the most authoritative tabulations of these agreements to be found to date appeared in a GDR publication, *Einheit* in June 1975.<sup>8</sup> At that time it listed 46 different intra-CEMA “international agreements” including the large multilaterals.

Most of the small, bilateral and trilateral agreements promote a relatively intensive degree of economic coordination and cooperation in highly developed industrial areas and within a small geographic area. As the leading industrial country in CEMA Eastern Europe, the GDR is a partner in nine of the 13 bilaterals mentioned by *Einheit*. These include an association for production of footwear with Czechoslovakia, one for textiles and cotton yarn with Poland, film with the USSR (*Assofoto*) and chemicals and metal forms with the USSR. There is also a Polish-Hungarian joint enterprise, *Haldex*, for the manufacture of construction materials from coal-mine slag, a joint Bulgarian-Hungarian enterprise, *Intransmash*, for manufacture of machines for internal factory transport, and the Novovolynsk plant, noted above, for production of electric motors under GDR-Polish and Soviet auspices. Special Soviet agreements with Mongolia provide for development of Mongolian mineral resources and there are a number of Polish agreements with East European countries for maritime transport.

Summing up, this steadily increasing number of small, regional agreements, many of which might be regarded as joint ventures in the Western sense of the term, constitutes another aspect of integration which is largely unpublicized and unnoticed.

(H) *Mounting East European Indebtedness to the West: A Step Toward Further Dependence on the USSR?*

The upward swing in Soviet and East European indebtedness to the West, both through rising trade deficits and through massive borrowing in Western money markets, has been a significant recent trend in East-West economic relations. As have the Soviets, the East Europeans have been busily buying up Western capital equipment and technology in accordance with long-term development plans.

Unfortunately, however, the East Europeans appear less able to handle the resultant indebtedness than does the USSR. Some of the reasons are mentioned elsewhere in this paper: small economies, limited—if any—domestic sources of energy and raw materials, meager gold and hard currency reserves. Furthermore, these countries lack the

<sup>8</sup> *Einheit*, East Berlin, June 1975. Another account, in Polish, is “The International Economic Organizations of the COMECON Countries,” Zdzisław Osiecki, *Handel Zagraniczny*, Warsaw, April 1976.

Soviet Union's ability to insulate itself from the impact of Western inflation. Forced to maintain huge subsidies to protect their consumers from the increased costs of imports, they are under steady pressure either to raise internal prices or to borrow still more from the West.

Estimates of Soviet and East European hard currency trade deficits for 1976 alone, based on preliminary figures, are about \$4 billion for the USSR and about \$6.5 billion for Eastern Europe. Estimates on total (trade and financial) individual East European indebtedness to the West vary, but in the case of Poland a figure of \$10 billion has been mentioned, with a debt service ratio of about 45 percent.

The obvious way for the East European CEMA countries to bring their hard currency debts under control is to cut back sharply on imports and borrowing from the West and to make an equally sharp increase in exports. Whether they will be able to achieve this depends on many different factors, some of them, such as Western inflation, not subject to their control.

In the background, however, there is the continued possibility that this East European indebtedness will lead to further dependence on the Soviet Union and to a further tightening of CEMA integration. In the case of Eurodollar credits, for example, the USSR is generally regarded by Western bankers as the ultimate guarantor for the CEMA East European countries. And it is the Soviet Union's top credit rating, based partly on its possession of one of the world's largest national gold reserves, which enables most of these countries to continue to be able to acquire credits from Western banking syndicates.

To date there has been only one indication, and that not officially confirmed, of the appearance of this additional thread of East European dependence within CEMA. In the fall of 1976 it was widely and reliably reported that Poland had received a one billion ruble credit from Moscow. Its purpose was emergency assistance to help Poland in its precarious economic situation. But measured in terms of CEMA objectives this credit constitutes another link for stronger integration, along with such other links as the deterioration of East European terms of trade with the USSR, investment in Siberian energy projects and intra-CEMA plan coordination.

### III. POLITICAL GAINS: PRESTIGE AS AN INTERNATIONAL ECONOMIC ORGANIZATION AND CONTACTS WITH THE WEST

Concomitant with its internal economic expansion CEMA has also been developing a much stronger international political presence. Some of this has been concentrated image building, a concerted effort to change the Western view of the Council of Mutual Economic Assistance from that of a completely Soviet-dominated, rather ineffective group of East European states, frequently involved in historic, nationalistic rivalries, to a powerful, important international economic organization on a par with the Common Market or some of United Nations regional organizations. This drive to increase stature and worldwide acceptance has, of course, been greatly assisted by East-West detente and the sharp increase in Soviet and East European trade and economic relations with the Industrial West. And it has also been consistently promoted by Soviet foreign policy.

The main channels for building this stronger political dimension have been through political and economic contacts with non-socialist

countries and organizations; and special attention to the third world. CEMA negotiations with the EEC, the conclusions of special agreements with Finland, Iraq and Mexico, and the presence of observers from Laos and Angola at the 1976 Council meeting exemplify this new political side of CEMA which is still expanding.

(A) *Official Ties With UN Organizations*

Although the CEMA Secretariat appears to have had some occasional contacts with United Nations organizations in the late 1960's and early 1970's, formal contact did not really begin until the fall of 1974 when the UN agreed to extend observer status at the UN General Assembly in New York to both CEMA and the Common Market. This development received extensive play in the Soviet press. It was rapidly followed by CEMA observer accreditation to several UN regional organizations—the Economic Commission for Europe (ECE) in Geneva, the Economic Commission for Latin America (ECLA), and for the Far East (ECAFE).<sup>9</sup> UN regional organizations are regularly invited to send observers to CEMA Council meetings and to some of the higher level meetings in Moscow.

(B) *Agreements With Non-Socialist Countries*

Following in the steps of the EEC, CEMA has now concluded formal agreements with three "outside" countries, Finland, Iraq and Mexico, and there are a number of indications that agreements are contemplated with additional countries—mostly in the third world—over the next several years.

There has been some confusion regarding the exact nature of these agreements. In essence, they are a bilateral cooperation agreement between CEMA as an organization (the CEMA Secretariat representing the nine member states) and the non-socialist country. The latter does not acquire official observer status at CEMA meetings, something which continues to be reserved only for certain socialist states—Yugoslavia, North Korea, Vietnam. The non-socialist country which has a bilateral agreement is nevertheless invited to send representatives to major CEMA meetings and has numerous other contacts as noted below.

The CEMA agreement with Finland was signed in Moscow on May 16, 1973 and appears to have served as a model for the subsequent agreements signed with Iraq (June 4, 1975) and Mexico (August 13, 1975).<sup>10</sup> It established a joint Finnish-CEMA Commission which meets twice a year in alternate capitals. And beneath it there are a number of sub-groups for different economic areas—oil, natural gas, timber, chemicals, machine-building, shipping, mining, to name a few. These groups also have alternate meetings in different cities, arrange further sub-groups and study-groups.

In the particular case of Finland it appears that most CEMA activity has been concentrated on energy (oil and natural gas, both

<sup>9</sup> *Pravda*, May 5, 1975.

<sup>10</sup> The conclusion of this agreement with CMEA gave Finland political balance for its relations with the EEC with which it also signed an agreement in May 1973.

of which Finland imports from the USSR) and the chemical and timber industries. The various specialized chemical and timber industry commissions have, according to the Soviet press, proposed long-term agreements for mutual deliveries of certain types of chemicals, recommended specialization of production of different types of chemicals by plants in Finland and CEMA countries and proposed cooperation in production of cellulose through the sodium-oxide method which reduces environmental pollution.<sup>11</sup>

The CEMA agreements with Iraq and Mexico call for the establishment of similar joint commissions and sub-commissions, meetings in alternate capitals and a similar bureaucratic hierarchy which will—presumably—concentrate on the most logical sectors for expansion of trade and economic relations between the CEMA countries and Iraq and Mexico. Thus, in the case of Mexico, it appears that oil and natural gas will be subject to special attention.

Several developing countries have been mentioned as likely candidates for an agreement with CEMA—Colombia, Argentina, Guyana (which sent a Ministerial level observer to a January 1977 CEMA Executive Committee meeting in Havana), Afghanistan, India and Iran. Rumors wax and wane. They are encouraged by the fact that most developing-country leaders who visit Moscow are invited to make an official call at the CEMA Secretariat where they are cordially met by Executive Secretary Faddayev and his staff. There is no doubt that the possibilities for some form of association agreement are discussed during these visits but actual implementation appears to be a matter for much additional negotiation.

At first glance these CEMA agreements with countries outside of the CEMA bloc appear as rather innocuous and slow-moving, and not at all comparable to some of the EEC agreements with outside countries which contain important provisions for trade quotas and preferences. But their ultimate possibilities and implications should not be overlooked. In addition to giving an additional boost to CEMA's international image, they provide an available, parallel framework for expansion of economic relations and trade between the non-socialist country and the USSR, Eastern Europe and Cuba. And in the case of Latin American countries the fact that nearby Cuba is a full CEMA member gives them additional importance.

### *(C) Special Attention to the Third World*

In reviewing CEMA's expanding political posture, it is apparent that particular attention is being paid to developing countries. In 1973, for example, the International Investment Bank announced that it was organizing a special, one-billion ruble aid fund for developing countries. The Fund, part of which is in hard currency, has not yet, as far as is known, extended any credits, possibly because the IIB is still waiting for just the right type of project. Another CEMA-controlled fund for developing countries provides scholarships and grants for study in CEMA countries by students from the third world. In contrast to the IIB's fund, this one has been operational for several years.

<sup>11</sup> *TASS Vestnik*, Moscow, Feb. 5, 1975.

In addition to special funds, both CEMA banks maintain active correspondent relationships with the Inter-American Development Bank and the Asian Development Bank, and occasionally take part in Western-organized syndicate Eurodollar or Eurocurrency loans for developing countries. The special attention which the CEMA Secretariat gives to third-world leaders, visiting Moscow and the various invitations to LDC countries to send observers to CEMA Council meetings and other important meetings further indicate the emphasis being given to development of good ties, both political and economic.

#### (D) *Negotiations With the Common Market*

The dialogue between CEMA and the EEC on a possible agreement—which has been underway since the summer of 1973—has attracted considerable interest. On balance it appears to be a reasonable and almost inevitable development: the establishment of formal ties between two economic blocs representing most of Eastern and Western Europe, each containing nine countries and together accounting for 16 of the leading countries on the European continent.

In actuality, of course, the two groupings are quite dissimilar. The EEC is composed of nine relatively small, highly-developed West European countries which have accorded certain rights of supranationality to the EC Council in Brussels. CEMA consists of six small East European countries, some of them on the borderline between “developed” and “developing,” the Mongolian People’s Republic in Central Asia and Cuba in the Caribbean, both “developing,” and the USSR, a superpower which is partly in Europe and partly in Asia. Moreover CEMA, officially at least, strongly rejects the idea of supranationality and emphasizes national sovereignty and the “interested party” principle for its members.

It seems to be partly because of this considerable divergency, and also for various other reasons, such as the high percentage of CEMA trade with the EEC versus the rather low share of EEC trade with CEMA, that the latest EEC response to a CEMA proposal for a comprehensive agreement has been less than satisfactory as far as the CEMA Secretariat is concerned. The EEC response suggests a rather limited agreement which would be concerned with exchange of information and statistics, some joint study groups and occasional joint consultations of experts.

Despite this slow pace of negotiations, it should be kept in mind that the fact that they are taking place at all is significant since they amount to a *de facto* Soviet (and CEMA) recognition of the Common Market. This has been further emphasized by the recent Soviet agreement to recognize the EEC 200-mile limit on fishing rights. And they have also given important additional support to CEMA’s public image as an organization equivalent to the Common Market.

#### IV. SOME OLD AND NEW PROBLEMS

The political and economic gains which CEMA has achieved in recent years are in many ways impressive. But at the same time a number of obstacles continue to hamper the accomplishment of economic integration goals despite the carefully worked out, long-range plans of the Complex Program. Some have been in existence

since the CEMA organization was founded nearly thirty years ago and seem to be almost endemic in command-economy systems. Others are relatively new, the result of changes in the CEMA structure and some of the new East-West relationships which have evolved with detente. In the following we discuss five of them, some of which are closely related.

(A) *Internal Prices: Disequilibrium, Non-Comparability and Confusion*

The fact that internal, domestic prices in the USSR and in each of the six CEMA countries of Eastern Europe have virtually no relation to the production costs and to the demand factors which determine domestic prices in market-economy countries means that they are "disequilibrium prices" in comparison with the way prices are determined in Western countries. Instead of reflecting costs of labor, materials, transport, scarcities or over-supply, tremendous consumer demand or consumer lack of interest or apathy, they are rigidly fixed and maintained by a central planning authority. This may hold down inflation, as it exists in Western countries, but it results in a completely unrealistic price as far as Western yardsticks are concerned.

A second form of "disequilibrium" exists in the case of intra-CEMA foreign exchange rates. CEMA currencies are non-convertible. Their exchange rates for Western currencies and also for other CEMA-country currencies are arbitrarily fixed by their respective governments and are not in any way determined by the supply of and demand for a particular currency for trade, payment for services and other transactions. The Bulgarian Leva for example is currently fixed by the Bulgarian Government at an exchange rate of 0.956 Leva for one US dollar.<sup>12</sup> If there is a sudden, huge demand for Bulgarian Leva by tourists and by foreign importers who wish to buy Bulgarian goods the price of the Leva in dollars remains the same. Likewise, if there is virtually no demand for it, it still remains fixed at 0.956 to the dollar.

One result of these two disequilibria—in price formation and in foreign exchange rates—is that CEMA countries have for a long time used Western, that is, world market prices, in valuing all commodities in intra-CEMA trade. Thus, to take a hypothetical example, if Czechoslovakia ships 20 turret lathes to Bulgaria, the approximate price for similar models manufactured in the West and sold in international trade is first determined. If the average price for equivalent models manufactured and sold by the FRG, France, US and Swedish firms is about \$100,000 each, then the lathes are valued at this price (plus or minus certain adjustments) in Transferable Rubles. Once they are shipped to Bulgaria the Bulgarian indebtedness to Czechoslovakia as maintained on the books of the IBEC is increased by two million Transferable Rubles.

Proceeding further, Bulgaria may offset this new indebtedness almost immediately by shipping to Czechoslovakia industrial loading equipment (forklift trucks) valued at about two million Transferable Rubles, the price of each forklift truck having been determined by the price for comparable models manufactured by Western firms and exported in international trade.

If this resort to world market prices were *not* used, then the Czechoslovak and Bulgarian foreign trade organizations would be

<sup>12</sup> "East-West Markets," New York, April 18, 1977.

confronted with the Herculean task of trying to determine the true value of Czechoslovak turret lathes and Bulgarian forklift trucks in terms of each country's respective structure for internal prices, wages, costs, state subsidies, turnover taxes and other key elements. What is the value of a turret lathe made at a factory in Brno at a labor cost of X Czechoslovak crowns, at a materials cost of Z crowns which includes a plus or minus factor of state subsidies and turnover taxes amounting to Y crowns? Furthermore, the internal domestic price for these lathes may be much lower than apparent costs. And again, the *methods and factors* used in determining the Czechoslovak costs are different in varying degrees from those used in Bulgaria.

The fact that East European domestic pricing systems not only lack uniformity but are, reportedly, becoming even more divergent, inevitably retards plans for true multi-lateralism—both in intra-CEMA trade and in plans for establishing some form of currency convertibility, even to a limited degree.

### *(B) Persistent Bilateralism in Intra-CEMA Trade*

The problem of lack of comparability in determination of domestic prices outlined above leads to this second problem which has plagued CEMA since its earliest days. In the immediate postwar period economic autarky was the order of the day in the Soviet Union. Bilateral balancing in foreign trade, i.e. the value of Soviet exports for a given year to a particular country being kept almost equal to imports from it for the same period was the accepted practice. It was also followed by the East European CEMA countries, their trade with other socialist countries being settled through bilateral clearing, the establishment of swing limits and other standard clearing account mechanisms.

Over the three decades since the end of World War II autarky has gradually been replaced by such concepts as the "international socialist devision of labor" and "socialist economic integration". When the IBEC was created in 1964 one of its announced prime purposes was to foment multilateral trade within CEMA through the use of the Transferable Ruble. And according to IBEC public announcements multilateral settlements are increasing yearly.

Unfortunately, however, close scrutiny of IBEC's annual statements indicates that up to the present time more than 90 percent of all intra-CEMA trade conducted through IBEC is settled bilaterally. The Transferable Ruble credit balances which Poland may acquire from its exports to the GDR are not put aside for purchases from Bulgaria or Romania at some future date. Instead, almost all of them are used to pay for imports from the GDR.

In the absence of published, official Soviet and East European explanations for the meager progress in multilateral trading, it is only possible to speculate. One major reason appears to be the considerable inflexibility and rigidity which permeates foreign trade planning and administration in CEMA-country foreign trade ministries. Precise, detailed targets for exports and imports with each particular country are outlined in advance for the entire plan year, together with longer range targets for the five-year period. Prices are also fixed in advance for transport, storage, and processing. The concept of continually

balanced trade with each partner is still considered not only desirable but essential. Large imbalances, surpluses, payments deficits for unforeseen periods of time are in conflict with what might be described as "the ethic of socialist planning." They also reflect a lack of complete control which is an anathema in a planned, socialist society.

At the present time there is no indication that the current drive for centralized CEMA plan coordination, which appears to have made some progress in the area of foreign trade, will result in any increase in multilateral trade and payment settlements. On balance more intensive planning would seem to increase rigidity and bilateralism, rather than to reduce it.

### *C. The Mushrooming CEMA Bureaucracy*

Although precise data is impossible to obtain, there is reasonably good evidence that the overall CEMA bureaucracy—the Secretariat in Moscow, the two Banks, the intergovernmental organizations, the "international economic organizations," the various international associations and joint enterprises, the permanent commissions, to name some but not all of it—has probably more than doubled and possibly even tripled in size over the past 28 years. And the expansion continues. The creation of secretariats for the new cooperation agreements with non-socialist countries (Finland, Iraq, Mexico) for example, has added personnel in still another direction.

In addition to its sheer size, which now requires a staff of several thousand, this vast administrative apparatus is also far-flung. Although the Secretariat, which occupies an attractive new multi-story building, and other control offices including the banks, are in Moscow, many of the specialized organizations and commissions have their headquarters in other member countries. *Interkhim* is run from Halle in the GDR; *Intermetal* headquarters are in Budapest; *Interatominstrument* has its main offices in Warsaw; the central despatch center and control offices for the *Mir* electric-power grid are in Prague, as is the headquarters for the CEMA railway freightcar pool. *Interkhimvolokno* has central offices in Bucharest, *Interelektro* is based in Moscow and *Mongolsovtvetmet* is based in Ulan Bator. All of these organizations, including the Secretariat and the two banks, are staffed by "international civil servants," that is, by nationals of different member countries.

The sum total of this complex, international bureaucracy which, like Topsy, just keeps growing and growing, appears to be quite literally a sprawling CEMA empire extending from the Caribbean in the Western Hemisphere to the Gobi desert in Central Asia. And in accordance with Parkinson's law, its growth must inevitably cause more growth, more experts, more meetings, study groups, agenda, commissions, secretariats, travel vouchers, protocols, regulations and copies in quadruplicate, together with the duplication, overlapping, inefficiency and loss of tight control which accompany bureaucratic sprawl.

### *(D) Independents and "Free Thinkers"*

The official, outward appearance of CEMA is one of complete unity of views with the understanding that those who disagree can agree to disagree, free from any pressures which might be imposed

by supranationality. Thus, as stated above, the Complex Program and Statutes stress full recognition of each member's sovereignty. And in accordance with the "interested country principle", no member is required to join in any CEMA international organization or to subscribe to any new program unless it voluntarily wishes to do so.

It has long been apparent, of course, that national differences and disagreements occasionally arise at different meetings and at different levels. Some of these may stem from traditional, historic rivalries and antagonisms but it appears that the more significant conflicts are on such matters as method, management and policy.

The outstanding "dissident" (a word used advisedly) has been Romania. Time after time the Romanians, using their rights under the "interested country principle," have been the only member country to refuse to join a new CEMA program or organization. And then—significantly, as an indication of the near impossibility of *not* cooperating—they have joined it a year or two later. This was the case with the IIB which Romania finally joined in 1972; with *Interkhim* which was formed in 1969 and which Romania joined in December 1970; with the protocol on technical standardization which was adopted at the CEMA Council meeting in 1974 and which Romania signed in 1975; and with the CEMA organization for cooperation in the ball-bearing industry which was established in 1964 but which Romania did not join until eight years later in 1972.

Romania's footdragging, one step backward, finally one or two steps forward, to catch up, seems to have become almost a standard procedure for new CEMA organizations. And it has also been in the Romanian press and in Romanian economic and political journals that some of the sharpest attacks have appeared on the dangers of loss of national sovereignty and economic independence which can result from long-range CEMA integration plans—despite CEMA Secretariat assurances to the contrary.

The most recent example of Romanian refusal to "go along with the group," has been in regard to CEMA negotiations with the Common Market. As the dialogue between Moscow and Brussels proceeded through the years 1973–1975, the Romanians insisted that the CEMA Secretariat should not have the right to negotiate with the EEC on behalf of individual CEMA member states. This insistence continued through the fall of 1975. At that time the Romanians carried on negotiations with an EEC delegation on exports of Romanian textiles to the Common Market and also refused—apparently—to agree to a proposed CEMA declaration which would have favored CEMA Secretariat negotiations with the EC Council on behalf of all CEMA countries. One result of Romania's recalcitrance on this issue may have been the postponement of an extraordinary CEMA Council session which had apparently been scheduled to take place in Moscow in December 1975, just prior to the Twenty-fifth Party Congress of Soviet Communist Party (CPSU).

Although no other East European country has been as outspokenly or persistently independent as Romania, it is generally recognized that both Hungary and Poland are interested in various types of economic reform which differ from the rigorous, intensively centralized system practiced in the USSR. Polish and Hungarian economists have also been keenly interested in trying to establish

some form of convertibility for the Transferable Ruble, or at least taking some concrete steps toward some limited currency convertibility in CEMA countries which would be a first step toward breaking the strictures of bilateralism.

*(E) The Painful Orchestration of Soviet Energy and Raw Material Deliveries to Eastern Europe*

Nominally, the allocation of Soviet raw materials and energy for the CEMA countries of Eastern Europe would appear to be a fairly routine task, accomplished through annual bilateral trade agreements after the usual negotiations. And it would also appear as a relatively easy one for the controlled, orderly apparatus of socialist planning. In fact, however, the increasing pressures of Soviet internal requirements plus those of Eastern Europe have made this doling out of raw materials and energy a difficult matter for many years, and were an important incentive for Soviet insistence on East European participation in the large raw material development projects on Soviet territory. With the advent of the 1973 energy crisis there have been numerous indications that the annual apportionment for Eastern Europe has progressed from being merely difficult to an agonizing balancing act which can cause painful economic and political reverberations if any mistakes are made.

Some of the basic causes of this new problem are identical with some of the difficulties which have recently developed for many countries in the world, East and West, in the last quarter of the twentieth century; the increasing world-wide shortages of raw materials and energy, rising populations, accelerating consumer demand, rising growth rates, persistent, and sometimes rampant inflation.

The issue first came into sharp focus on the matter of Soviet oil deliveries to the CEMA East European countries in 1974. And oil continues to be a primary, and probably the most visible, indicator of the tensions involved. In essence, as noted in II(A) above, the USSR was faced with the problem of just how much oil it could afford to deliver to Eastern Europe at a cut-rate price, for payment in Transferable Rubles when every ton of oil shipped to Western Europe could earn two or more times as much in badly needed hard currency. The question was further complicated and exacerbated by the Soviet Union's unexpected hard currency deficits caused by large-scale purchases of Western capital equipment and technology during a period of Western inflation, and by unexpected emergency grain purchases, and also by the rapid expansion of the Soviet Union's own oil requirements.

For the Soviet leadership, and specifically for the top personnel in charge of foreign economic relations, the handling of the complex problem of energy and raw materials for CEMA Eastern Europe must inevitably be a delicate tightrope walk for which there is no long-term, automatic solution. The raising of intra-CEMA foreign trade prices can, in effect, be regarded as merely an internal adjustment which has not solved the basic problem and has in itself caused a number of others.

In the case of oil, for example, the Soviets appear to have set a definite limit on the amount they will provide for Eastern Europe

(approximately ten percent of the annual output) and to have decided to compel these countries to purchase additional quantities from world markets—for hard currency. But increased East European purchases from world markets (1) mean less dependence on the USSR and thus a certain reduction in integration and (2) require increased East European exports to hard currency markets, which is also a move away from dependence and integration.

The increased East European use of Soviet natural gas is one partial way out of this dilemma, and the all-out drive for completion of the Orenburg pipeline reflects a policy decision in this direction. But here again there is the persistent, nagging question of how much for CEMA allies and soft currency and how much for Western customers and Deutschmarks, Francs or Austrian Schillings. When the Orenburg project was first announced it appeared to be purely a CEMA project. Now there are indications that some of the gas will also be exported to Western Europe. And Soviet gas from other lines in the USSR will also be exported westward in increasing quantities.

This same dilemma, how much for the East European fraternal socialist countries, how much for the West and how much for ourselves (the USSR) can also be applied to Soviet plans for exports of all other commodities—coking coal, copper, cellulose, asbestos, timber, cotton, chrome ore, apatite and even industrial diamonds. It must inevitably result in long, painful negotiating sessions before bilateral agreements are concluded in Moscow or in East European capitals.

In addition to omnipresent economic strains, this enigma of energy and raw materials allocation also poses political problems in Eastern Europe which can be even more acute, more dangerous. The disturbances which erupted in Poland in May and June 1976, indicate what can happen if an East European economy comes under too much strain, becomes too imbalanced. Hence the balancing act. How to keep the relatively fragile economies of Eastern Europe on keel, how to meet the growing internal and foreign exchange requirements of the Soviet Union? How to avoid political strains, cracks and explosions, and how to keep the entire political and economic mechanism which makes up the CEMA-Warsaw Pact bloc operating smoothly?<sup>13</sup>

The answers must not be easy. And it seems that in order to maintain this desired political and economic harmony, there must be much disharmony, many denials of requests, much acrimonious negotiation, a constant pushing of buttons, pulling of levers, tightening up here, easing up there—with the overall objective of not only maintaining socialist economic integration but making progress at the same time.

## V. CONCLUSIONS

The Council of Mutual Economic Assistance is not a dramatic organization. Viewed from the West it lacks some of the glamor of the Warsaw Pact or the CPSU Congresses in Moscow or the new political force referred to as Eurocommunism. Because for a long time, from

<sup>13</sup> The one billion ruble credit reportedly extended to Poland by the U.S.S.R. in the fall of 1976 is one example of emergency action being taken to keep an East European economy on balance.

1950 to about 1970 it was relatively ineffective and also because it is very complex, often obscure and at times hard to understand, it is frequently dismissed by many Western observers as a not very efficient, Soviet controlled apparatus which will probably not succeed. Or, if it does, will not succeed very well.

In many respects, however, CEMA is like the bumble-bee which according to the laws of aeronautical engineering, cannot fly because its wings are too small for its body; but, never having heard of aeronautical engineering, the bumble-bee flies anyway.

Evaluated on the eve of its 30th anniversary, there can be no doubt that the organization has made important progress, especially since 1970. The launching of the Complex Program in 1971 was followed, just two years later in 1973, by the world energy crisis which, from the viewpoint of Soviet and CEMA Secretariat objectives, could hardly have been more fortuitous. The upheavals of 1973 and 1974, and the worldwide inflation and shortages which will apparently continue for the foreseeable future, have given a tremendous boost to East European economic dependence on the USSR. It is difficult, of course, to measure the exact degree of this dependence and it is still in process of development. But added to the geographical, political and military ties which these countries already have with the Soviet Union, it is an impressive fact.

Also impressive is the continued expansion of CEMA infrastructure, both physically, in such areas as pipelines, power grids, transport and raw material-energy development projects, and administratively in the large number of specialized organizations—economic, industrial, technical, financial and even political. Most impressive of all are the indications of the beginnings of low-level, regional supranationality—co-production, joint investment, joint management at the enterprise rather than the governmental level.<sup>14</sup>

As noted in this paper's introduction, CEMA is moving slowly but steadily forward. There are indeed many serious problems, just as the Soviet Union itself has many problems in its own economic development. It would appear, however, that at present time is on the side of "socialist economic integration" and that over the next two decades there is a good possibility that CEMA will become increasingly stronger and more effective.

<sup>14</sup> Several days after completion of this article the Soviet press (*Pravda* and *Izvestiya*) on April 16, 1977, published the official communique of the 80th meeting of the CEMA Executive Committee which had convened in Moscow from April 12 through 14. The Communique is particularly interesting for its indication of continued top-level attention to some of the points which are mentioned.

*Inter alia*, the Executive Committee (1) approved cooperation in joint (several country?) machine-tool production using numerical control systems; (2) approved the formation of a new International Economic Association, *Interodochistka*, which will be concerned with environmental protection and cleaning of water resources and will have its headquarters in Bulgaria; (3) noted the continued importance of expanding multilateral payments in intra-CEMA trade through the use of the Transferable Ruble and discussed ways in which this can be done; (4) approved a new system of exchange of consumer goods between CEMA countries (details not mentioned); (5) discussed increased CEMA cooperation with socialist and developing countries which are not members of CEMA, specifically "the development of economic and scientific-technical cooperation with the Socialist Republic of Vietnam, the People's Democratic Republic of Laos, and also the People's Democratic Republic of Angola;" (6) discussed the "inquiry of the Cooperative Republic of Guyana regarding the establishment of cooperation relations" with CEMA; (7) discussed further steps towards development of relations with the EEC; and (8) approved a report on the activities of the CEMA observer delegation at the 31st session of the United Nations General Assembly.

## ABSTRACT

This paper analyzes recent developments concerning Soviet and East European efforts to arrange negotiations between the European Community (EC) and the Council for Mutual Economic Assistance (CMEA) on an agenda of trade and cooperation issues important to one or both sides. It discusses the underlying political and economic realities and perceptions which favor such negotiations, and those which serve as major impediments. Although at present the EC has shown an unwillingness to engage in discussions, this paper concludes that the CMEA countries will continue to push for such negotiations and that the EC will most likely agree. It seems unlikely, however, that the resulting agreements will have a major impact on trade flows in Europe. Certainly all foreseeable agreements would appear to contain no important implications for U.S.-CMEA or U.S.-EC trade.

---

\*Prepared at the University of Texas under contract for the Bureau of East-West Trade, U.S. Department of Commerce. I am grateful to several people in the Bureau and the Department of State for comments on an earlier draft of this paper which served to improve it. The remaining errors and all opinions are mine.

## INTRODUCTION

*The Subject of the Paper*

In recent years the Council for Mutual Economic Assistance (CMEA)<sup>1</sup> and the European Community (EC)<sup>2</sup> have begun to cautiously explore the possibilities of framework agreements on economic relations between their respective member states. In 1974 as the EC Common Commercial Policy (CCP) took effect, all bilateral trade agreements between individual EC members and the CMEA countries expired. In their place the EC proposed draft trade agreements between the Community (which by then controlled all external trade relations with "state-trading" countries) and individual CMEA countries. In the interim until the CMEA countries responded to the draft bilateral trade agreements, the EC Commission declared (on November 12, 1974) that it was now giving state-trading countries MFN with respect to tariffs and that the scope of imports subject to quotas in 1974 remained the same in 1975.<sup>3</sup>

In 1976 CMEA responded with a proposed CMEA-EC framework agreement covering trade, credits, cooperation, and so on. In late 1976 the EC rejected the CMEA proposal, which is where the situation stands at present. Both sides are slowly outlining negotiating positions, and it is doubtful that an agreement of substance will soon emerge.

The attempt by CMEA to negotiate a trade agreement, in fact *any* agreement, with the EC itself is a dramatic turnabout from earlier, particularly Soviet, policies concerning the EC. In the late 1950's the USSR held that an economic union such as the EC would soon disintegrate due to severe contradictions among the member states. In the early 1960's, the position changed to one of admitting that the EC had survived over the short term but that its long-term prospects were dim. Finally in the 1970's, in light of the EC's success in stimulating trade, and its enlargement to nine members, the Soviets seemed to admit that indeed the EC was functioning well enough that they should consider formally recognizing it and dealing with it, a process which is just now beginning.<sup>4</sup>

This paper seeks to analyze the economic and political issues surrounding CMEA-EC economic relations, to predict on the basis of that what the eventual outcome may be regarding the substance of EC-CMEA relations, and then to assess what implications these developments might have for U.S. relations with the CMEA countries.

<sup>1</sup> Currently CMEA has nine active members: Bulgaria, Cuba, Czechoslovakia, East Germany, Hungary, Mongolia, Poland, Romania, and the USSR. My concern in this paper is only with the European members, which are by far the most important ones. As I have shown elsewhere, in the case of Cuba its "membership" is a very special one which is not nearly as active as might first appear. (See my "An Analysis of Cuba's Membership in the CMEA" a paper presented to a conference on "The International Relations of the Cuban Revolution," sponsored by the Ibero-American Language and Area Center, NYU, October 31-November 1, 1975.)

<sup>2</sup> The term *European Community* is now the formal term applied to three communities—the European Coal and Steel Community, the European Atomic Energy Community and the European Economic Community—since their unification under one set of governing bodies in 1967. Practically all that is said here refers only to the EEC, nevertheless I shall use the more general term, and for simplicity I shall use it even for the brief discussion of the pre-1967 period. The members of the EC are Belgium, Denmark, France, Germany, Ireland, Italy, Netherlands, Luxembourg, and the United Kingdom.

<sup>3</sup> *Bulletin of the European Communities* (11/74), 14.

<sup>4</sup> There are many discussions of the evolution of Soviet policy towards the EC. For one which includes developments up to about two years ago, see Ileana G. John, "The Soviet Response to Western European Integration," in the book he edited entitled *EEC Policy Towards Eastern Europe* (Lexington: Lexington Books, 1975), 37-58.

This introductory section outlines the present CMEA and EC positions on a framework agreement. The second section discusses the economic and political factors behind CMEA initiatives toward the EC. That section shows that developments in the CMEA are an important determinant of the future of the EC-CMEA dialogue, therefore the third section discusses developments in CMEA in the 1970's. Then the final section discusses the probable future course of EC-CMEA relations, and the implications that course would have for U.S. relations with East and West Europe.

*The EC Position on Relations With the CMEA Countries*

Until the late 1960's the EC had no official position on trade with the CMEA countries. But as the Community moved to solidify its control over external trade relations of the members, it began to develop a Common Commercial Policy (CCP) towards "state-trading" countries, for our purposes, towards the CMEA countries. In anticipation of agreement on the CCP, the EC Council of Ministers agreed in 1970 to a Commission proposal that from then on all trade agreements between EC members and CMEA countries spanning more than one year would include a clause stipulating that the agreement could be modified if the CCP required it.<sup>5</sup> In 1972 one of the announcements from the Summit Conference of the Nine was that the CCP would come into force on January 1, 1973, and that most bilateral agreements between CMEA countries and individual EC members would end in 1974, with the remainder expiring in 1975. Henceforth CMEA countries would have to negotiate agreements with the EC Commission.<sup>6</sup> In May 1974 the Council of Ministers indicated the EC's willingness to negotiate trade agreements with individual CMEA countries. Receiving no response, it approved a draft bilateral trade agreement on November 7, and sent it on to each CMEA country a few days later.<sup>7</sup>

The draft proposed that in trade between the EC members and each CMEA country, they should agree—

1. On non-preferential trade relations (e.g., no special concessions in the Common External Tariff) based on reciprocal assurance of equal benefits and obligations;
2. On mechanisms for solving commercial difficulties between countries;
3. On mutual granting of Most Favored Nation (MFN) treatment with respect to tariffs, subject to the customary exceptions (e.g. special preferences for LDC's); and

<sup>5</sup> John and Pauline Pinder, *The European Community's Policy Towards Eastern Europe* (London: PEP, 1975), 17. The EC Commission and Council of Ministers are the only two institutions there which are important to this paper. The Council is the main legislative organ of the EC and consists of one minister representing each member-state. Its decisions are binding on the member states. The Council can only, however, consider proposals submitted to it by the Commission, a body composed of thirteen members appointed by common consents of the member state governments. The Commission is the executive body of the EC and its work is supported by the bureaucracy, the Directorates General. In addition to these two institutions, the Parliament with 198 members at present appointed by member-government parliaments is primarily consultative; it reviews commission proposals before they are submitted to the Council. An example of all this is the proposals concerning the implementation of the EC CCP for "state-trading" countries. The proposal was submitted by the Commission to the Council. The Council could not have considered it if the Commission had not submitted it; but the Commission can only propose it without any formal power to act on it. For a brief and easily readable introduction to the EC see George W. Hoffman and J. Warren Nystrom, *The Common Market* (2d ed.; New York: D. Van Nostrand Company, 1976).

#### 4. On establishing joint committees and 'safe-guard' mechanisms concerning market disruption.

It was also mentioned that "... provisions for the agricultural sector would not be ruled out."<sup>8</sup> A subsequent EC report on EC-CMEA relations made it clear this latter statement could not be construed to mean that the EC was willing to negotiate with CMEA any aspects of its Common Agricultural Policy (CAP).<sup>9</sup>

No individual CMEA countries responded to the proposed trade agreement, rather the collective response was contained in their counter-proposal of February 1976 for a CMEA-EC framework agreement, which is discussed below.

The other important developments within the EC which affected EC-CMEA relations involved the successful efforts by EC member states to retain individual control over non-trade aspects of commercial relations with CMEA. In 1966 the French successfully defended their position that policies concerning credits to the CMEA countries were part of their foreign policy, therefore not subject to the authority of the Commission. Consequently there is no common credit policy for the EC. Also, the Community has no formal authority over *cooperation* agreements, except as those agreements impinge on trade matters; therefore here also the individual EC member-countries act independently. In an attempt to minimize some of the potentially divisive consequences of autonomy in these important areas, the Council of Ministers has set up an informational exchange procedure through which individual countries are supposed to regularly exchange information on their credit policies and on the cooperation agreements which they have signed. Also there has been some discussion on the possibility of Community-wide cooperation agreements and financing for projects with CMEA countries too large for individual members to handle.<sup>10</sup>

The Community has only limited control over the quotas its member-states place on imports, particularly imports from CMEA. Most EC countries had removed quotas on the majority of imports by the late 1960's, retaining quotas on imports of sensitive products, including some quotas directed specifically at CMEA countries. At present the EC countries have agreed on a Common Liberalization List on which they record all products where quotas have been liberalized. After those products are so recorded, quotas cannot be reimposed without common consent by the entire Community. However there is no common quota list for the Community, and no common list of discriminatory quotas for imports from CMEA countries.<sup>11</sup>

This division of power between the Commission and the member-states has important implications for EC relations with CMEA. The CMEA countries have a very strong preference for negotiating intra-governmental trade and cooperation agreements since they are so closely interrelated. Yet the Community has authority only in the area of trade; in other areas the EC member-states retain consider-

<sup>8</sup> *Bulletin of the European Communities* (11/74), 13.

<sup>9</sup> R. A. Klepsch, *Report on the European Community's Relations with the East European State-Trading Countries and COMECON*. Prepared for the Committee on External Economic Relations. Document 425/74 (January 1975), 20. The CAP is discussed below.

<sup>11</sup> John and Pauline Pinder, *The European Community's . . .*, 19 and 23.

able autonomy. Thus while the EC complains of the lack of authority on the part of the CMEA in negotiating trade agreements; it is likewise true that the Commission has no authority in negotiating *cooperation* agreements, which would include provisions on credits, industrial cooperation, joint ventures, and so on.

### *The CMEA Position on Relations With the EC*

CMEA did not directly respond to the EC draft bilateral agreements, rather in early February Gerhard Weiss, then Chairman of the CMEA Executive Committee, transmitted to the Commission a proposed framework agreement between the CMEA and the EC.<sup>12</sup> The most important propositions in the proposed agreement are:

1. Reciprocal granting of MFN treatment on the basis of existing agreements, or new ones where applicable;

2. Relations to be based on non-discrimination, including the removal of all trade barriers save those applied to all "third" (non-EC) countries (#1 probably refers to tariffs while this provision is aimed at non-tariff barriers, especially quotas);

3. A market disruption clause;

4. An agreement to develop stable, long-term trade in agricultural products, and to give up any restrictions on trade which do not apply to all third countries;

5. Discussions on currency problems with the goal of finding ways to allow the continuous growth of commerce, and an agreement on mutually favorable credit conditions;

6. A stipulation that signing this agreement does not affect the rights of individual states in either the EC or CMEA to sign agreements with states or the international organizations on the other side;

7. Establishment of a joint commission composed of representatives of the CMEA, the EC, and their respective member states; and

8. Cooperation in the areas of standardization, the environment, statistics, and predictions of consumption and demand of selected key products.

CMEA publications have referred to the CMEA proposal as a "draft agreement", yet it is only part that, and part an agenda for further discussion. It does indeed propose that the sides offer each other MFN, make moves to remove all discriminatory measures, and so on. On the other hand, it proposes that they *discuss*, for example, agricultural trade, currency issues, and cooperation on important problems. And in fact if the CMEA draft agreement were accepted as a guide to discussions, and if the discussions came out with decisions as outlined in the draft, then the EC draft bilateral agreements would fit quite well as allowable discussions (under point 6 above) between the EC as a whole and individual CMEA states. Also, the CMEA draft proposal seems to outline quite well the major issues which

<sup>12</sup> As far as I know the text has only been published in German in Jochen Bethkenhagen and Heinrich Machowski, *Integration im Rat für gegenseitige Wirtschaftshilfe, Entwicklung, Organisation, Erfolge und Grenzen (Integration in the Council for Mutual Economic Assistance: Development, Organization, Successes, and Limits)*. Berlin: Verlag, 1976), 125-30. I am grateful to Maria Otto for her translation of the text. The essentials of the agreement are discussed in several places. See, for example, V. Zoloev, "Vazhnaia Initsiativa SEV" ("An Important Initiative of CMEA"), *Vneshniaia torgovlia* (5/76), 24; or Max Baumer and Hanns-Dieter Jacobsen, "Institutional Aspects of East-West Economic Relations," *Journal of World Trade Law* (1976), 443ff.

require negotiation: credits, MFN, elimination of other trade barriers, agriculture, and general issues surrounding economic cooperation. Where the CMEA differs from the EC is in the scope of discussions they propose.

On the surface at least the main issue which impedes the beginning of discussions along the lines suggested in the CMEA draft agreement is a disagreement between the EC and CMEA on the powers which the CMEA has to negotiate on such matters. In November 1976 the EC rejected the CMEA draft proposal giving as its justification the rationale that the CMEA is essentially powerless in trade matters, and hence is not an appropriate negotiating partner for the EC Commission.<sup>13</sup> That position reflects a long-held view within the EC that CMEA indeed does not possess such supranational powers, and that the Commission should do nothing to encourage the development of such powers with the consequences that could have for the autonomy of small East-European states vis-a-vis the Soviet Union.<sup>14</sup> Actually under the present CMEA Charter in force since June 1974 the organization itself has the authority to ". . . conclude international agreements with member-countries of the Council, with other countries, and with international organizations."<sup>15</sup> This is an extremely vague phrase which gives CMEA a technical response to the charge that it has no power to negotiate agreements for its members, without specifying what types of "international agreements," or just how the individual CMEA member states will protect their interests. On the other hand, the CMEA Secretariat could well claim that the EC really has much more limited authority than the CMEA since the EC Commission is confined in its activity to trade issues only, while the CMEA Secretariat covers the entire spectrum.<sup>16</sup>

But obviously these debating points are not the substance of the real impediments to negotiations; rather they are symptoms of some very important issues. The next section considers the major political and economic issues surrounding the CMEA-EC dialogue.

## POLITICAL AND ECONOMIC CONSIDERATIONS IN THE EC-CMEA DIALOGUE

### *Introduction*

The fact that there is potential for an EC-CMEA dialogue given the real political impediments to such a process suggests that one or both sides see some potentially substantial economic benefits flowing from the successful outcome of such negotiations. One question of interest here is, therefore, what economic interests both sides bring to negotiations, and on the basis of those interests on what issues will they seek to negotiate?

<sup>13</sup> *New York Times* (11/16/76).

<sup>14</sup> R. A. Klepsch, "Report on the European Community's . . .", 23.

<sup>15</sup> Article III.2.b of the CMEA Charter as amended according to a protocol signed on June 21, 1974. For copy of the text, see *Ekonomicheskoe sotrudnichestvo stran-chlenov SEV* (May 1975), 109-112.

<sup>16</sup> At least one Soviet economist has articulated just such an argument. See K. I. Popov, "Problemy razvitiia ekonomicheskikh svyazei stran-chlenov SEV so stranami 'Obshchego rynka'," in N. P. Shmelev (ed.) *Problemy ekonomicheskogo sotrudnichestva mezhdru vostokom i zapadom evropy (Materiali mezhdunarodnoi konferentsii uchenykh-ekonomistov stran SEV i Jugoslavii, sostoiavsheisia v Moskve 9-12 Oktabria 1972 g.)* (*Problems of Economic Cooperation Between Eastern and Western Europe (Material of an International Conference of Scientists-Economists of the CMEA Countries and Yugoslavia convened in Moscow, 9-12 October, 1972)*. (Moscow: Adademia Nauk SSSR, Institute Mezhdunarodnoi Sotsialisticheskoi Sistemy, 1973), 80.

But the fact that the CMEA-EC dialogue is so slow in starting testifies to the extremely complex and important political considerations which could attend such talks and the resulting settlement. In particular it seems clear that at present the EC is more impressed with the negative political consequences of such negotiations than on their potential economic benefits. Therefore this section also discusses the political considerations which seem to impede the progress of preliminary talks.

### *Major Economic Issues*

To understand the major economic issues in the CMEA-EC dialogue it is useful to begin with some of the basic characteristics of the trade between countries in these two regions. Table 1 contains trade data for 1965-66 and 1974-75 for all West European Trade with CMEA countries, about 60 percent of which is EC-CMEA trade.<sup>17</sup>

TABLE 1.—WEST EUROPEAN TRADE WITH ALL OF CMEA, THE SOVIET UNION, AND THE REST OF CMEA, AVERAGES FOR 1965-6 AND 1974-5.

<sup>1</sup> SITC categories: 0+1—Food, live animals, beverages, and tobacco; 2+4—Crude materials, excluding fuels, and animal and vegetable oils and fats; 3—Mineral fuels, lubricants, and related materials; 5—Chemicals; 6+8—Manufactured goods classified chiefly by materials, and miscellaneous manufactured goods; 7—Machinery and transportation equipment; and 9—Goods not elsewhere classified.

<sup>2</sup> The 1965-6 data were broken down into SITC 6+8 and 9, while the 1974-5 data were broken down into SITC 6, and 8+9. Therefore I have simply combined all 3 groups for purposes of comparison here.

Sources: 1965-6 data: Paul Marer, "Soviet and East European Foreign Trade" (Bloomington: Indiana University Press<sup>\*</sup> 1972), 224, 231, 233, and 239. 1974 data: United Nations Economic Commission for Europe (UNECE), "Economic Bulletin for Europe" (prepublication copy), vol. 27(1975), 67-8. 1975 data: UNECE, "Economic Bulletin for Europe" (prepublication copy) vol. 28(1975), table 3.4.

West European exports to CMEA, and to the USSR and other members separately, are highly concentrated in manufactures, 76 percent in 1965-6 and almost 89 percent in 1974-5. And it is here in technology-bearing machinery, equipment, and intermediate goods (such as chemicals) where Western Europe hopes to continue to develop export markets in the CMEA countries.

<sup>17</sup> I have resorted to SITC data for all of Western Europe in order to include 1975 data, since those data are not yet available for trade of the EC 9 with CMEA, and since 1975 was an important year in East-West trade. In the last year for which I have comparable data, 1973, the structure of all West European trade with CMEA and EC-9 trade with CMEA is virtually identical on exports and very close on imports. The discussion focuses here on the structure of trade, therefore these data are adequate.

West European imports from CMEA differ in their structure for the USSR and the remaining CMEA members. About half of the imports from the USSR are liquid fuels, primarily oil, but with an increasing amount of natural gas; in addition some primary products (SITC 2+4) are important such as timber and plant fibers. Imports from the small CMEA countries show no remarkable concentrations in one product group, as one might expect given the resource endowments of those countries. Imports of manufactures are much more important than from the USSR, and the share has increased substantially, from 38 percent in 1965 to 55 percent in 1974-5. In addition the small CMEA countries rely on food and beverages (fruit, vegetables, meat, and live animals) for a substantial portion of their export proceeds, 18 percent in 1975-4; although that has fallen from 32 percent in 1965-6.

The most important issue for the EC in negotiations with the CMEA countries would probably involve improving access for EC manufactures on CMEA markets. This could mean, for example, more industry representatives with offices in the CMEA capitals; better information on plans and product demands of enterprises, associations, and ministries; and possibly even some limited input into the planning process through, for example, a CMEA-EC joint commission. EC interests in securing fuels and primary products might translate in the negotiations into discussions on long-term contracts, direct investment in the Soviet Union, and so on. Here there would be much less controversy than in matters concerning the first issue.

Finally, what the trade data do not show is the EC firms' interest in investments in CMEA through joint ventures or other nonparticipatory forms of industrial cooperation. Here also one might expect that in the negotiations the EC might seek mechanisms to ease access to CMEA factors of production.

The CMEA countries bring different interests to the negotiations, and there are sharp differences in the concerns of the USSR and Eastern Europe. The Soviet Union is an enormous country with an abundance of natural resources, and it can be expected to push hardest on interests which follow naturally from its comparative advantage. The Soviets will show an interest in enormous projects on Soviet soil where western money capital and machinery exploit primary product and fuel resources now, with the resulting products shipped to West Europe later. Issues surrounding those projects—credits, EC-wide coordination of supply of machinery and demand for the products, government participation, and so on—will dominate much of their discussions at the sessions. Soviet comparative advantage lies primarily in natural resources and they will seek to negotiate ways to use international trade and capital to exploit those resources.<sup>18</sup>

Unlike the Soviet Union, the other CMEA countries rely for a substantial portion of their foreign exchange earnings in Western Europe on agricultural and food products (included in SITC 0, 1, and 4), and exports of those products run head-on into the EC Common Agricultural Policy (CAP) which is undoubtedly one of the

<sup>18</sup> For a strong statement of that position see, e.g. the recent article by V. Alkhimov (Deputy Minister of Foreign Trade, USSR), "Razvitiia vneshneekonomicheskikh svyazei SSSR v svete reshenii XXV s'ezda KPSS," ("The Development of the Foreign Economic Ties of the USSR in Light of the XXV Congress of the CPSS"), *Vneshniaia torgovlia* (7/76), 2-9.

most effective Community-wide policies which have been enacted.<sup>19</sup> The small CMEA countries, and for that matter the U.S., would very much like to see changes in CAP, but the complex and important internal political issues surrounding it preclude changes in response to CMEA pressure.

With the exceptions of Poland and Romania, the small CMEA countries' export prospects in primary products and fuels are practically nil. What is left then is manufactured goods. Consequently in comparison to the Soviet Union, Eastern Europe can be expected to bring to the negotiations a much stronger interest in discussing the CAP, and a much stronger need to obtain concessions for its manufactured goods exports.

There is, then, no obvious commonality of interests between the small CMEA countries and the EC, however there may be some grounds for negotiations, at least in the area of manufactured goods. The burgeoning industrial cooperation agreements between East and West have proved that the small Eastern European countries do have a relative abundance of cheap labor, which can best be exploited in a multiplicity of small cooperation agreements between a number of enterprises. It may be therefore that the small CMEA countries and Western Europe will find their common interests in negotiating better conditions for the realization of these types of agreements as a way to increase exports of manufacturers to Western Europe. These are far less dramatic than the large agreements which interest the Soviets, but they can be quite profitable to both sides.

These are the major issues which negotiations would touch on, and the list could be extended. The Soviet Union in particular seems to see a great deal of potential for mutual gain from economic cooperation in Europe, and it envisages large projects not only in primary products, but in other areas such as research and development, transportation, power transmission, and the environment; and has pushed some of these projects for years.<sup>20</sup> And one can see in the CMEA draft agreement that the major issues which interest the USSR and the other CMEA countries are all included.

For purposes of this paper it is not important to list all of the issues which would come up in the negotiations; what is important is to realize that there are major substantive issues with which negotiations could deal. One well known datum to keep in mind here is that, measured by the relative proportions in total trade, trade with CMEA is not nearly as important to the EC as trade with the EC is to CMEA. About 5% of EC trade is with CMEA, and about 15% of CMEA trade is with the EC. By that measure the potential relative

<sup>19</sup> The CAP consists of a system of support mechanisms for intra-EC agricultural prices and a system of variable levies to make sure that imported prices stay above internal prices, thus guaranteeing an advantage to domestic producers. In recent times as world agricultural prices have risen dramatically, the CAP has worked in the opposite direction by putting levies on exports in order to divert potential exports to the domestic market, thus keeping domestic prices below world market prices for many products. This latter feature gives a rather ambiguous character to the CAP since when world market prices for agricultural goods are quite high (compared to intra-EC prices), the CAP diverts potential EC agricultural exports to the rest of the world as a consequence pushing up prices of those products; on the other hand it diverts demand away from potential importables and drives those prices down. For a brief discussion of the CAP see Michael Berendt, "The Common Agricultural Policy," in *European Studies*, No. 19 and No. 20 (1974). There is also some more detailed useful material in a document published by the EC Commission entitled "Stocktaking of the Common Agricultural Policy," 2/75 Supplement to the *Bulletin of the European Communities*.

<sup>20</sup> For two recent discussions which outline the Soviet view of what Europe could be, see I. Kormnov and I. Petrov, "Razriadka napriazhennosti i khoziastvennoe sotrudnichestvo," ("Relaxation of Tensions and Economic Cooperation,"), *Voprosy ekonomiki* (2/76), 57-67; and Y. Shirayev and A. Ivanov, "Detente: Economic Implementation," *International Affairs* (10/75), 23-32.

economic benefits of any settlement they reach are probably much smaller for the EC than the CMEA. Consequently while there are substantive economic issues of interest to both sides, they may seem much more important to CMEA than to the EC. It is probably for this reason that the EC shows much more concern for the political consequences of negotiations than the CMEA; it can afford it.

### *Political Issues*

There are political consequences to both sides from negotiations. For the CMEA, particularly the Soviet Union, it means recognition of a political-economic union which they have scoffed at for years. A Soviet decision to accede to the Common Commercial Policy, negotiate with the Community as a whole, and cease attempts to negotiate on trade matters with individual EC members, would serve to strengthen the power of the Commission relative to individual member states. This plus the mere fact of recognition would seem to be high political costs for the USSR. It is not clear if the economic benefits of negotiations would compensate. The EC countries need primary products and fuels, which the USSR has, and the lack of a framework would hardly act as a major impediment to investment and trade in those products. On the other hand, as long as there are major restrictions on U.S. government guaranteed credits, then the EC as a whole and Japan are the only two groupings large and rich enough to finance the large projects the Soviets have in mind; thus the Soviets could perceive large potential economic benefits of working through the EC.

A second, and possibly strong argument, is that the economic costs to the other CMEA countries of not negotiating with the EC are potentially quite large, large enough to have political consequences in Eastern Europe, and therefore political consequences for the USSR. The small CMEA countries are seeking to penetrate markets of larger countries in an increasingly powerful EC. East Europe has pushed the Soviet Union for years to recognize the reality of the EC and deal with it.

The catalyst seems to have been enlargement from six to nine members in the EC. Before enlargement the EC contained three of the top five destinations (in value terms) of total CMEA exports to developed market economies (dme's). Enlargement added yet another: England. In addition it was not clear then, and still is not clear, what effect the Association Agreements between the EC remaining EFTA countries would have on CMEA exports (which includes Finland the fifth major export source; Japan is the only major dme trade partner not affected).

These considerations served as the backdrop for what appears to have been a very important conference in Moscow in October 1972 attended by economists from all of the CMEA countries and Yugoslavia on the topic of "Problems of Economic Cooperation Between Eastern and Western Europe."<sup>21</sup> The themes common to most of the papers by the East European economists were that the EC was on its way to encompassing most of the major western export markets

<sup>21</sup> The papers are published in Shmelev (ed.), *Problemy ekonomicheskogo sotrudnichestva* . . .

of CMEA, and that it was time therefore not only to recognize the existence of the EC but to negotiate with it and to negotiate with it as a united organization. The words of two Czech economists are representative of the views of many economists there:

It seems to us that to ignore the existence of the EC in the new situation would be extremely short sighted. However it is inadequate to only passively recognize the existence of the EC; in the future it would be appropriate to relate to it actively, that is to endeavor through coordinated actions of the member-countries of CMEA to establish stable institutionalized contacts to have an affect on the EC with the goal of preventing the . . . negative consequences connected with its enlargement.<sup>22</sup>

The Hungarian economists in attendance were very strong on coordinated action toward the EC:

Experience proves that a coordinated trade policy of the capitalist countries can be opposed with success only by a coordinated trade policy of the socialist countries. It would be precisely thanks to that [policy] that the EC would be forced to refrain from introducing a common commercial policy in relation to the socialist countries.

The socialist countries can more effectively defend their interests only if individual member-countries of CMEA will act, operating on the strength of the entire socialist community, and more than that, coordinate the content and time period in force of specific trade policy measured.<sup>23</sup>

The position of other East European economists could be cited, but it would be repetitive, since they all contend in one way or another that it is time for the CMEA countries to recognize the EC—in particular its Common Commercial Policy—and to realize that only a socialist “common” commercial policy can adequately fight a capitalist “common” commercial policy.

That conference in 1972 among primarily academic economists who probably advise policy makers, but do not themselves make policy, cannot be taken as the final word on East European policy towards the EC and towards a coordinated CMEA approach to the EC. The consequences of enlargement may look less frightening five years later, and the consequences of coordinated action may seem somewhat more threatening to the sovereignty of individual East European countries.

As far as I can see at least in the Hungarian press there is very little talk now of the need for coordinated action towards the EC.

Nevertheless there is probably a substantial base of support in Eastern Europe for carefully using the CMEA to negotiate with the EC. Eastern Europe has genuine negotiable needs in its trade with the EC, which become more important as the power of the CCP and CAP grow. The size of individual East European countries precludes their negotiating effectively with the Community as a whole. If the small CMEA countries seek concessions from the EC on the CCP or CAP, one obvious approach for them is to enlist the aid of the Soviet Union through CMEA.<sup>24</sup>

<sup>22</sup> I. Nikl and S. Tikal, “Puti rasshireniia ekonomicheskoi svyazi mezhdu vostochnoi i zapadnoi evropoi,” (Means of Expansion of Economic Connections between Eastern and Western Europe”), in Shmelev (ed.), *Problemy ekonomicheskogo sotrudnichestva* . . . , 65.

<sup>23</sup> Zh. Khavash, “Nekotorye uslovia dal'neishego razvitiia ekonomicheskikh svyazi ‘Vostok-Zapad’” (“Several Conditions of the Further Development of ‘East-West’ Economic Relations”), Shmelev (ed.) *Problemy ekonomicheskogo sotrudnichestva* . . . , 91.

<sup>24</sup> One of the few works I have seen which shares my view of the East European position on CMEA-EC negotiations is Peter Marsh, “The Integration Process in Eastern Europe 1968 to 1975,” *Journal of Common Market Studies*, XIV, 4 (June 1976), 311-35. Also the Pinders have suggested that for reasons already outlined above the East Europeans unofficially suggested to EC officials that they would like to see CMEA-EC negotiations on a framework of principles, within which detailed bilateral negotiations could ensue between the Community and individual CMEA members. See John and Pauline Pinder, *The European Community's* . . . , 29-30.

EC policy-makers seem to assess Eastern Europe's position somewhat differently. They see the major potential political cost of negotiations with the CMEA to be that such negotiations might serve as a way for the Soviet Union to enhance its economic and political power in Eastern Europe, something which Eastern Europe does not want, and which they therefore should do everything possible to discourage.<sup>25</sup>

What is involved here is a basic perception which EC politicians and many scholars have concerning the CMEA which is hopefully not overly simplified in three hypotheses:

1. The CMEA as an organization is powerless on substantive issues in the area of economic relations; member states retain all the powers of decision in those areas.

2. The small Eastern European countries prefer that state of affairs.

3. Actions of the EC could enhance the power of CMEA, and therefore the power of the USSR in the economic affairs of the small CMEA countries.

It has already been shown that No. 2 is probably not true at least on the particular issue of CMEA-EC relations. The first point represents the conventional wisdom, and in fact some of my writing supports such a view.<sup>26</sup> Nevertheless it would appear that in the last five years the CMEA has begun an important transformation under Soviet guidance which could, in the end, result in an extremely powerful supranational organization; and Eastern Europe may be cautiously supporting those developments. To the extent this is true it means that the EC, like the CMEA did with the EC earlier, is ignoring recent developments or at least underestimating their importance for the power of CMEA as an organization. A more accurate understanding of those developments, which will come with time, could substantially change EC policy towards CMEA. The following section addresses itself to recent developments in CMEA in order to show how the functions of that organization may be changing.

## RECENT MOVES TOWARDS STRENGTHENING THE CMEA

### *Introduction*

The history of CMEA through the late 1960's has been discussed in detail by many authors and only the few points of importance to this analysis need be recounted here.<sup>27</sup> Throughout that period CMEA was an extremely weak organization, at first one of several vehicles for Soviet control of Eastern Europe, and later an organization where some genuine discussion on the fundamental economic issues surrounding CMEA trade occurred, but with no action. CMEA had, and has, no powers to do more than recommend policies to the various countries on substantive economic issues concerning trade, specialization, prices, currency, and so on. Important decisions required bilateral or multilateral negotiations among decision-makers

<sup>25</sup> See for example I. G. John, "The Soviet Response . . .", 53ff and M. Baumer and H. D. Jacobsen, "Institutional Aspects . . .", 442-3.

<sup>26</sup> Edward A. Hewett, *Foreign Trade Prices in the Council for Mutual Economic Assistance* (Cambridge: Cambridge University Press, 1974), Chapter I.

<sup>27</sup> See, for example, M. Kaser, *Comecon* (2d ed.; Oxford: Oxford University Press, 1967); E. A. Hewett, *Foreign Trade Prices . . .*, Ch. I and VI; and Z. M. Fallenbuhl, "East European Integration: COMECON," in U.S. Joint Economic Committee, *Reorientation and Commercial Relations of the Economics of Eastern Europe* (Washington: Government Printing Office, 1974), 79-134.

in CMEA countries; and while CMEA itself could bring representatives of those decision-makers together, it could not make decisions, nor could it force individual countries to make decisions. It had, and has, no supranational powers.

The highest organ in CMEA is the *Council* (Soviet) which is comprised of delegations from each country led by a deputy prime minister. In the 1950's and 1960's there were some sessions of the Council where the prime ministers themselves attended; several meetings of party leaders (sometimes as Extraordinary Sessions of CMEA); and one Extraordinary Session where both party and government leaders attended (in 1969, the XXIII Session). It was in these forums that collective decisions on substantive issues were made.<sup>28</sup>

Usually the Council meets once a year, and in the interim an *Executive Committee* comprised of the deputy ministers watches over the progress concerning Council recommendations. In addition there is a *Secretariat* of the Council with the usual duties. Finally there are *Standing Commissions* which are devoted to certain sectors (for example, electric energy, machine building, agriculture, and ferrous metallurgy) or certain functional areas (for example, foreign trade, standards, statistics, and currency questions). Each of these Standing Commissions has as its task the encouragement of cooperation in the area of its concern (specialization in production where that applies), and it is composed of representatives from appropriate organizations in each country. The Standing Commissions derive their power from, and are subordinate to, the Council, consequently they have absolutely no decision-making power; they can only *recommend*, for example, specialization in the production of certain products in an industry.

The "Basic Principles of the International Socialist Division of Labor" (hereafter, simply Basic Principles) serve as an excellent example of the powerlessness of CMEA during these years. This was a set of recommendations on specialization in the CMEA which it took four years to negotiate, and which proposed, in a set of internally contradictory statements that the CMEA countries should specialize and trade according to comparative advantage in order to reap the gains from trade in the form of increased efficiency.<sup>29</sup> The recommendations were about a general methodology to guide specialization so that efficiency would be increased without hampering balanced development of any CMEA member. The Standing Commissions were to produce real recommendations on specialization for their sectors; but the Basic Principles were too vague and contradictory to serve that purpose. In any event, CMEA could only use the Basic Principles to generate recommendations with no binding force on individual states.

Khrushchev, dissatisfied with the essentially meaningless propositions in the Basic Principles, proposed in 1962 that the CMEA undertake to coordinate investments in large projects as a tangible way to guarantee specialization and improved efficiency. But Romania successfully fought off what it considered to be an attack on its sovereignty, and CMEA remained powerless in economic affairs.

<sup>28</sup> For details, see E. A. Hewett, *Foreign Trade Prices . . .*, 7-8.

<sup>29</sup> For a discussion, see E. A. Hewett, *Foreign Trade Prices . . .*, 3ff.

### *The Comprehensive Program*

It was in 1969 in the aftermath of Czechoslovakia that the USSR began a move to strengthen CMEA. The April 1969 Extraordinary Session (XXXIII) of party and government leaders initiated a major discussion on reform of CMEA institutions which resulted finally in 1971 in the "Comprehensive Program,"<sup>30</sup> This is an enormous, complicated, and contradictory plan for a total reform of CMEA through the 1980's. There is neither space nor need to discuss most of its provisions here, and instead the focus is on those of particular interest to what has transpired since then in the area of plan coordination.

It was the Soviet view, which was built into parts of the Comprehensive Program, that there were substantial gains possible from improved economic cooperation among the CMEA countries and that plan coordination would most effectively allow the CMEA members to capture those gains. In particular the Comprehensive Program proposed that the CMEA countries undertake to coordinate their long-term and five-year plans much more carefully, that they undertake joint prognoses on major economic aggregates, that they actually undertake joint planning for the production and consumption of selected products, and that they conduct regular exchanges of information on the nature of economic reforms in their respective countries. While these activities would involve coordination of efforts at various levels in the planning hierarchies of each country (ministries, departments, combines, enterprises), the Soviet view was that the major effort would be at the level of central planners with extensive consultations with all other levels.

Several tangible changes in CMEA surrounded the approval of the Comprehensive Program at the XXV Session of CMEA in 1971. The International Investment Bank had begun operation that year, its purpose being to provide financing for investments of interest of more than one CMEA member, and ultimately to finance large CMEA-wide investment projects connected with the Comprehensive Program.<sup>31</sup> Also, several Committees on Cooperation were set up, one on Planning and one on Science and Technology (hereafter: Cooperation Committee on Planning and Cooperation Committee on Science and Technology). These are both important committees, primarily because the delegates from each country are the heads, respectively, of each country's planning committee and each country's highest organ concerned with science and technology. In the CMEA hierarchy they are considered as committees of the Council, and they can give tasks to the Standing Commissions, as well as submit recommendations for the consideration of the Executive Committee and the Council.<sup>32</sup>

<sup>30</sup> *Kompleksnaia programma dal'neishego uglubleniia i sovershenstvovaniia sotrudnichestva i razvitiia sotsial'no-ekonomicheskoi integratsii stran-chlenov SEV (Comprehensive Program for the Further Deepening and Improvement of Cooperation and the Development of Socialist Economic Integration of the Member-Countries of CMEA)* Bucharest: Soviet ekonomicheskoi vzaimospomochi, 1971). Unless otherwise indicated, this discussion is based on E. A. Hewett, *Foreign Trade Prices* . . . 181-190.

<sup>31</sup> This was approved in 1970 and was the result of a proposal coming out of one of the seven working groups whose reports comprised the final Comprehensive Program. Some of the reports, or part of them, were approved at the XXIV Session of CMEA in 1970, and the IIB proposal was one of those.

<sup>32</sup> Their formal names are *Komitet SEV po sotrudnichestvu v oblasti planovoi deiatel'nosti* (Committee of CMEA on Cooperation in the Area of Planning Activity) and *Komitet SEV po nauchno-Tekhnicheskomu sotrudnichestvu* (Committee of CMEA on Scientific-Technical Cooperation). The distinction between these Committees and the Standing Commissions is important since the former have much greater authority. Also one would suspect that *de facto* the Cooperation Committee on Planning is the most powerful single organ in CMEA, possibly more so than the Executive Committee, since delegates are probably much more influential in their own countries than the deputy prime ministers who sit on the CMEA Executive Committee.

No other major changes occurred around this time. There was the normal spate of articles on the progress made to implement the Comprehensive Program, and it appeared that nothing terribly substantive would emerge. However Soviet pressure to transform CMEA continued and intensified after the signing of the Comprehensive Program and now, six years later, it is evident that indeed important changes have begun to come about.

### *New Moves To Implement the Comprehensive Program*

There are a number of indications of significant changes in CMEA. Every Session of the Council since 1970 has been attended by the prime ministers themselves. The Cooperation Committees have taken on a fairly important role, and a new one concerned with "Material-technical supply" has been added.<sup>32a</sup> In particular they prepared a rudimentary 1976-80 five-year plan for all the CMEA countries which committed each country to substantial investments and other actions, which the countries in turn wrote into their five year plans; there is, in other words, now a five year plan for CMEA. A type of long-term plan is also emerging under the title of "Target Programs" (*tselovye programmy*, in Russian; *célprogramok* in Hungarian) which outline long-term plans in selected sectors.

There are other symptoms of the changes, but these are among the most important, and in discussing them, one can get a genuine feeling for the nature of the changes which have occurred to date. Certainly, as will be evident, there is much in these "new" efforts which simply represents fancier titles for old programs, combining separately negotiated projects under one heading, and so on. But what is being discussed here is important not so much for what has been done concerning 1976-80, but for the framework which could be used to generate some fairly comprehensive, joint plans for the 80's.

#### THE CMEA "FIVE-YEAR PLAN"

In June 1975 the XXIX Session of CMEA passed the "Coordinated Plan of Multilateral Integration Measures for 1976-80" (hereafter: Coordinated Plan).<sup>33</sup> Its public roots lie in the XXVII Session in June 1973 where the Council directed the Cooperation Committee on Planning to "... focus its activity on elaborating effective ways of resolving the problems of economic cooperation in the area of satisfying the demands of the member-countries of CMEA for basic forms of energy and fuel, including atomic energy, and the deepening of cooperation of the countries in the development of primary product sectors."<sup>34</sup>

By June 1974 at the XXVIII Session there was already discussion of a "Coordinated Plan".<sup>35</sup> Then at the XXIX Session in June 1975, Baibakov (Chairman, USSR Gosplan) reported on the work of the Cooperation Committee on Planning and submitted a draft proposal

<sup>32a</sup> This committee was set up in 1974 at the XXVIII Session of CMEA. At present it is not apparent what its role will be.

<sup>33</sup> In Russian: "Soglasovannyi plan mnogostoronykh integratsionnykh meropriatii na 1976-1980gg". There is no easy translation for "Soglasovannyi"; it literally means "agreed upon". I am going by the Hungarian word for the same plan, "koordinált", or "coordinated".

<sup>34</sup> XXVII Session Soveta ekonomicheskoi vzaimopomoshchi" (XXVII Session of the Council for Mutual Economic Assistance"), *Ekonomicheskaja Gazeta*, no. 24 (June 1973), 20.

<sup>35</sup> N. V. Faddeev, "Vo imiaikh velikikh tselei," ("In the Name of Great Goals"), *Ekonomicheskaja gazeta*, no. 28 (July 1974), 20.

for the Coordinated Plan; which the Session accepted.<sup>36</sup> The plan itself has not been published, so it is necessary to rely on secondary sources for its content; unfortunately no authors have fully discussed the entire plan, so what follows is a mixture of piecing together several sources and guessing.

There are several sections to the plan which cover international specialization and cooperation in production; joint projects for developing major primary product and fuel resources, primarily in the USSR, but also in Cuba and Mongolia; and cooperation in scientific-technical matters. In each case there are supposedly agreed upon measures with corresponding resource commitments built into the five-year plans of each CMEA country participating in the process.<sup>37</sup>

The section on the joint projects appears to be by far the most tangible and carefully worked-out part of the Coordinated Plan.<sup>38</sup> There are ten projects included in this section, of which no more than eight actually have accompanying contracts among the participating countries. Eight projects are contemplated for the USSR, of which the five on which arrangements seem fairly advanced are:

1. The Ust' Ilinsk *Kombinat* for the production of Cellulose.
2. The Kiembraevskii Asbestos *Kombinat*.
3. A 750 KW electricity transmission line from Vinitza through the Western Ukraine to Albertersha in Hungary.
4. The Orenburg gas pipeline to the western border of the USSR.
5. Expanded capacity for the production of iron-bearing primary products and several types of ferro-alloys.<sup>39</sup>

Evidently three other projects to be on Soviet soil are now being negotiated, including one for producing isoprene rubber and one for fodder yeasts. In the case of the isoprene rubber, construction on the project will not begin until after 1980.<sup>40</sup>

In addition agreements have been signed for the expansion of Nicle production in Cuba through the reconstruction of some enterprises and the construction of one new one. A project in Mongolia concerning coking coal is under negotiation. Also, projects are under consideration on copper, molybdenum concentrate and titanium dioxide.

Of the probably eight projects where actual funds have been committed the estimates are that investment costs will total 8-9 billion

<sup>36</sup> For a discussion of Baibakov's draft see N. K. Baibakov, "Soglasovannyi plan mnogostoronnikh integratsionnykh meropriatii—novaia stupen' razvitiia sovmestnoi planovoi deiatel' nosti stran-chlenov SEV," ("The Coordinated Plan of Multilateral Integration Measures—A New Stage in the Development of Joint Planning Activity of the Member-Countries of CMEA," *Planovoe Khoziaistvo* (9/75), 9-12. A discussion of the XXIX Session can be found in N. Ptikhin, "XXIX Sessia Soveta Ekonomicheskoi Vzaimopomoshchi," ("The XXIX Session of the Council for Mutual Economic Assistance"), *Vneshniaia torgovlia* (10/75), 2-7.

<sup>37</sup> N. Baibakov, "Soglasovannyi plan. . ."

<sup>38</sup> This discussion on the joint projects contains information pieced together from four sources: I. Inozemtsev, "Reshenie toplivnoenergeticheskoi i syr'evoi problem—na planovoi osnove," ("The Solution of Fuel-Energy and Primary Product Problems—on a Planned Basis."), *Ekonomicheskoe sotrudnichestvo stran-chlenov SEV* (4/75), 14-19; K. Grikhish and I. Portiannikov, "Nekotorye voprosy koordinatsii narodnokhoziastvennykh planov stran-chlenov SEV na 1976-1980 gg.," ("Several Questions about the Coordination of Economic Plans of the Member-Countries of CMEA for 1976-1980"), *Ekonomicheskoe sotrudnichestvo* . . . (5/75), 43-5; B. Ladygin and O. Rybakov "XXV s'ezd KPSS i uglublenie sotsialisticheskoi ekonomicheskoi integratsii," ("The XXV Congress of the CPSS and the Deepening of Socialist Economic Integration"), *Voprosy ekonomiki* (11/76), 76-84; and L. I. Zorin, "Na vzaimovygodnoi osnove," ("On a Mutually Profitable Basis"), *Vneshniaia torgovlia* (8/76), 10/13.

<sup>39</sup> These include several cooperation projects with West German enterprises as well as a contemplated CMEA project, although the latter has been postponed until after 1980. (Interview material)

<sup>40</sup> Ladygin and Rybakov, "XXV s'ezd . . .", 81.

Transferable Rubles (TR's) over the 1976-80 period.<sup>41</sup> TR's are not like other Rubles, so it is risky to say what that means in terms of total CMEA investment expenditures. But I would say that 9 billion TR's will work out at somewhere between 1% and 2% of the total investments of the CMEA countries during 1976-80.<sup>42</sup> So the Coordinated Plan is a five-year plan for a very small part of investments.

Apparently the Soviet Union is paying about half of the investment costs.<sup>43</sup> The Eastern European countries will pay their share either by shipping products necessary for the construction projects themselves such as metal products, bulldozers, cement, cables, pipes, and so on; consumption goods which will be sold in the USSR to finance the construction; and in some cases, labor. Hungary, for example, had 1000 workers working on Orenburg in 1976,<sup>44</sup> and they had planned to ship 700 Ikarus buses to the Soviet Union in 1976 as partial payment for the pipeline.<sup>45</sup> They had also shipped in 1975 1 thousand tons of structural steel for the plant.<sup>46</sup> The IIB is providing hard-currency credits to the CMEA countries so that they can buy the equipment needed for these projects which they themselves do not produce.

Repayment by the USSR for all of the projects is in the form of the output, usually spanning a twelve year period. For example, in the case of Ust'-Il'msk, repayment will be over twelve years at an average payment to every participating country of 50 thousand tons a year.<sup>47</sup>

In some cases the projects will have a substantial impact on production and trade within the CMEA in the products in question. For example the Nickle project in Cuba is projected to increase production of Nickle by 130 thousand tons per year, which is over three times the level of current Cuban production (36.8 thousand tons per year) and over half of the level of 1975 Soviet production (210 thousand tons).<sup>48</sup> The Orenburg pipeline's completion will raise Soviet shipments of natural gas to Eastern Europe by 15.5 thousand cubic meters per year, which is about 1.5 times current shipments.<sup>49</sup> Finally, the projected output of 500 thousand tons per year of cellulose from Ust'-Il'msk is

<sup>41</sup> The 9 Billion TR figure can be found in several places, e.g. Ladygin and Rybakov, "XXV s'ezd . . .", and in the communiqué on the XXV Session (*Ekonomicheskaja gazeta*, 27 [June 1975], 3). The low figure is from L. I. Zorin, "Na vzaimovyygodnoi osnove," 1. He makes it clear that this figure is for only eight of the ten projects eventually contemplated, and it could be that the other sources are including estimates for the two projects not yet finalized.

<sup>42</sup> An official of the IIB has estimated that during 71-5 the total investment of all CMEA countries was about 500 billion TR's. (See A. Belichenko, "Investitsionnyi bank-vazhnyi instrument sotsialisticheskoi ekonomicheskoi integratsii," ("The Investment Bank—An Important Instrument of Socialist Economic Integration,"), *Vneshinaia torgovlia* [8/76], 28-32). That figure is actually about ½ of what obtains by taking total investment figures in national currency and converting at the official exchange rate into Soviet Rubles (which have the same gold content as TR's, hence the same official exchange rate). But those rates are meaningless, and I suspect that Belichenko was using the coefficients which are used in CMEA to convert non-commercial transactions into TR's. In those cases, the procedure is to convert at official exchange rates into Rubles, then divide by a coefficient of 2 to 2.2 (See Adam Zwass, *Monetary Cooperation Between East and West* [White Plains: International Arts and Science Press, 1975], 75-6). That would give about 550 billion TR's.

Then if that figure is right, the 9 billion TR cost of the joint projects would have been a little less than 2 percent of 1971-5 investments in CMEA as a whole, therefore probably closer to 1.5 percent of 1976-80 investments.

<sup>43</sup> L. I. Zorin, "Na vzaimovyygodnoe osnove," 11.

<sup>44</sup> D. Seker, "Novye cherty y ekonomicheskoe sotrudnichestvo," ("New Features in Economic Cooperation"), *Ekonomicheskaja gazeta*, 50 (December 1976), 20.

<sup>45</sup> *Figyelő* (2/25/76), 7.

<sup>46</sup> L. Shinkarev, "Ust'-il'meskii fundament," ("The Ust'-Il'msk Foundation"), *Ekonomicheskoe sotrudnichestvo stran-chlenov SEV* (3/75), 80.

<sup>47</sup> Shinkarev, "Ust'-il'mskii fundament," 80.

<sup>48</sup> The estimate of the increase in nickle production is from Ladygin and Rybakov, "XXI s'ezd . . .", 81. The estimate of current nickle production is from U.S. Central Intelligence Agency, *Handbook of Economic Statistics 1976* (ER-76-10481; 1976), 98.

<sup>49</sup> The estimate of the increase in gas shipments is from Grikkish and Portiannikov, "Nekotorye voprosy . . .", 45. Estimates of 1975 Soviet gas shipments to Eastern Europe are 10.691 thousand m<sup>3</sup>, from *Vneshinaia torgovlia SSSR za 1976 godu*.

somewhat less than 10% increase over total CMEA production of Cellulose in 1974.<sup>50</sup>

In summary, one could say that the joint projects of the Coordinated Plan represent only a tiny portion of total investment in the CMEA countries in 1976-80, but should they be realized as planned, their impact on the output of particular products will be substantial. This is by far the best articulated part of the Coordinated Plan, and judging from the multitude of articles, the part about which the Soviets are the most proud. It is not all new; some of the projects had been signed before the Coordinated Plan was even officially titled.<sup>51</sup> But the projects are quite possibly very important for what they indicate could happen in CMEA in the future. Just as the enormous planning apparatus in the USSR began in plan construction for electrification, that is, for an energy project, so could planning in CMEA conceivably develop from these modest beginnings.

The other parts of the Coordinated Plan appear to be far more nebulous; they are rarely discussed, and we will not discuss them here. Also, there is, at least formally, more to what is called "plan coordination" than the Coordinated Plan, such as discussions on trade in major products over the next five years, R&D plans, and so on. But the Coordinated Plan appears to be the most effective part of plan coordination activities in the CMEA; it is certainly the part to which the Soviets give the most attention.

#### THE CMEA "LONG-TERM PLAN"

In addition to the five year plan, the XXIX and especially the XXX Session (July 1976) of CMEA discussed a set of long-term plans which have come to be grouped under the heading of "Complex Target-Programs."<sup>52</sup> These are programs spanning 10-15 years designed to combine forces in CMEA for the solution of key problems associated with their further industrialization. There are five programs:

1. *Fuel, Energy and Primary Products.*—The main goal here is to assure adequate supplies of these materials over the long term. The emphasis is both on rational use and economizing on the demand side, as well as increasing domestic fuel supplies in each CMEA country. This program also includes all provisions on atomic energy.

2. *Machine-building.*—Here the purpose is to develop supplies of machinery in deficit areas, particularly as they relate to the other Target Programs.

3. *Agriculture and Food Supply.*—This program is aimed towards attaining CMEA self-sufficiency in cereals, fodder, animal products, and other food products, as well as forming sufficient reserves.

<sup>50</sup> The projected output of Ust'-Il'msk is from Zorin, "Na Vzaïmovygodnoi osnove," 11. The estimated output for all of CMEA is taken from separate country data in *Statisticheskii ezhegodnik stran chlenov SEV za 1975 godi*. (Statistical Yearbook of the Member-Countries of CMEA for 1975).

<sup>51</sup> For example, the general agreement on building the Kiembaevski Asbestos Plant was signed at the XXVII Session of CMEA in June 1973. See V. Zolov, "Pervoe general'noe soglashenie" ("The First General Agreement,"), *Vneshniaia torgovlia* (7/73), 33-37.

<sup>52</sup> In Russian, *Kompleksnaia tsel'programmy*; in Hungarian *Komplex célprogramok*. In both cases *tsel'/cel* means goal or target. The discussion which follows is taken from János Szita, "A szocialista gazdasági integráció útján (A Kölszövetség Gazdasági Segítség Tanácsának XXX ülészaka)", ("The Road of Socialist Economic Integration [The XXX Session of the Council for Mutual Economic Assistance]"), *Közgazdasági szemle*, XXIII (9/76), 1005-29.

4. *Consumption goods*.—This project involves forecasting changes in demand, and changing the supply of consumption goods to offer a broader choice of products and higher quality products.

5. *Transport Connections*.—This program is devoted to improving substantially transport and transfer capacity in CMEA countries, since at present the projections show demand outpacing capacity in the mid-1980's.

Details on these programs really do not at this stage go much beyond what is indicated above, thus the "long-term plan" is even more embryonic than the Coordinated Plan as a five-year plan. In fact at this stage the Target Programs really appear to be statements that long-term projections in these areas indicate the need for planners to do something; just what needs to be done has not yet been planned. Still, these are potentially quite important programs for several reasons. They form an institutional basis for mutual projections of demands and supplies of important groups of products by CMEA for the CMEA countries as a whole. That means they will force discussions on shortages and surplus before they arise, not afterwards. They may indirectly influence planners to change their plans; and conceivably they could be a vehicle for pressure through the Cooperation Committee on Planning for planners to make changes in their plans. The information which comes through joint projections in such areas as energy or food could be a tremendous catalyst, forcing planners to recognize CMEA-wide problems and take CMEA-wide solutions.

Of course the Soviets are in favor of this procedure, but so might be some East European planners. For example Szita seems to be genuinely enthusiastic about the prospects of these programs, and in fact their character is very similar (in name and function) to programs undertaken in Hungary in the last decade. Eastern European industrialization prospects for the future hinge on energy and raw material imports, and if they can obtain from the USSR long-term quantitative commitments for those products, they would probably regard themselves as much better off than having to rely on world markets at uncertain prices for their new supplies. That is why the joint projects—which some view as a burden on Eastern Europe—quite possibly make good economic sense. Eastern Europe faces the certain need of energy and raw material imports and it has two choices. It could invest in industries which will produce exportables, export those goods and, depending on the terms of trade, receive a certain amount of primary products and fuels in return. Or it can invest directly in the USSR for those primary products and know with certainty what it will receive in return. The second route could be cheaper, depending on productivity in export industries, marketability of those goods and world markets, and the terms of trade in comparison to the prices on other arrangements in the deal with the USSR. At the very least there is no obvious case for saying that the joint projects are exploitative. And in fact I suspect that Szita's rather enthusiastic support of the Target Programs reflects the opinion of some planners in each East European country.

*The Significance of Recent Development in CMEA*

What is happening now in CMEA may or may not represent a move towards enhanced supranational authority for the CMEA on a broad scale. It is really too early to say with any certainty.

On the one hand it is fairly clear that the Soviet Union has begun a concerted effort to develop a planning apparatus in CMEA similar to the USSR planning apparatus. The committee structure, personnel, techniques, and tasks bear striking resemblance to the USSR planning system. One can imagine the image in the mind of some Soviets of a CMEA with a strong supra-Gosplan (The Committee on Coordination in Planning), a supra-Committee on Science and Technology (The Committee for Cooperation in Science and Technology), a supra-Price committee (not yet formed, but there are conferences of price officials), and so on. They truly believe that such a system would bring improved economic performance to all the CMEA countries individually and collectively.

But besides this belief in central planning—which goes way back in the Soviet view of the proper role for CMEA—there are other forces pushing to strengthen CMEA, of which the most important would seem to be:

1. General problems in economic performance in all save the least developed CMEA countries, primarily stemming from an inability to find an adequate source of rapid growth to substitute for exhausted reserves of surplus labor. These problems are a major concern to all CMEA politicians, particularly since in some cases they lead almost directly to political problems, such as those in Poland in 1970 and 1976. These events threaten the political and economic cohesion of CMEA, and therefore stimulate the Soviets to find solutions through CMEA to the economic problems which are among their causes.

2. The success of West European efforts at economic integration which have had two effects. Indirectly the Soviets see CMEA as a tool for competition with Western Europe, particularly the EC, and therefore at least part of the Soviet motives towards improving the functioning of CMEA have their roots in the success of the EC. Also the specific fact of the success of the EC stimulates the CMEA countries to think of strengthening their organization as a necessary bargaining tool.

3. The crisis in the world economy has had a particularly strong effect on the East European economies, but far weaker than it would have been, had not the USSR continued to ship fuels at prices below the world market (although higher than earlier). Thus there is an incentive for Eastern Europe to use CMEA as a way to reach agreements with the USSR on reducing the uncertainty of supplies of products crucial to production—fuels and primary products.<sup>53</sup>

Thus there are several sets of considerations pointing to a strengthened CMEA, and they are not all limited to Soviet aspirations for

<sup>53</sup> For elaborations of these points see, e.g., Z. M. Fallenbuehl, "East European Integration . . .", 97ff, and Peter Marsh, "The Integration Process . . ."

CMEA. But the interests of Eastern Europe lie in achieving a strengthened CMEA for a rather narrow set of products—fuels and primary products where certainty serves their purposes quite well—without simultaneously losing authority in other areas such as the sectoral product mix, the supply of consumer goods to their population, and so on.

Not all of the information is available, but so far it would appear that Eastern Europe has managed to keep the centralization of power in CMEA within the bounds they prefer. There is no coordination of annual plans, which are the operational plans in most CMEA countries that really determine what will be produced, by whom, and for whom. There is only coordination of five-year plans, and those are frequently a mixture of political posturing and serious planning which economic and political realities frequently render obsolete.

Also for the plan coordination that is most effective in CMEA—covering a five-year period—the available evidence indicates that the only serious coordinated planning occurred on the fuels and primary products, which is just where the East European planners would want such coordinated planning. Plan coordination in, say, machine-building does not seem to be much more advanced now than it was in the late 1960's.

It will be a substantial achievement if Eastern Europe can continue to walk this tight-rope of agreeing to, and possibly even encouraging, the development of coordinated planning, but directing it only towards projects it needs badly. And if that occurs, then the future for the CMEA five-year and long-term plans seems a limited, but still important one, of coordinating investment and trade in primary products and fuels.

It is impossible to predict with any certainty what will actually transpire in the future. First, public sources alone provide an incomplete indication of what has transpired in the past, and what public sources do not reveal may indicate much stronger trends than are here evident. Also events inside CMEA could change the pressures a great deal. On the one hand further unrest in CMEA could mobilize Soviet leaders to push even harder for a major recentralization of powers in CMEA as they seek to use their planning techniques to deal with the economic roots of unrest. Or the world economic crisis could eventually create unbearable tensions in the EC, say through balance of payments problems, and therefore reduce somewhat the threat of the EC for the CMEA. And it is quite conceivable that the increased role of communist parties in western Europe could significantly change the policy of the EC towards CMEA.

At the very least it seems likely that CMEA-wide planning is here to stay on a minimal scale for the medium and long-term plans. The question is what consequences that will have for East-West Trade, for relations between the EC and CMEA and, for U.S. trade with CMEA and the EC.

#### THE FUTURE OF CMEA-EC RELATIONS AND THE CONSEQUENCES FOR THE U.S.

We now turn to a consideration of what type of agreement will most likely emerge between the EC and CMEA, and an assessment of the affect that agreement would have on U.S. relations with CMEA

and Western Europe. It is useful to separate these and consider first the development of CMEA-EC relations, then their potential impact on the United States.

### *The Future of EC-CMEA Relations*

The EC so far has refused to negotiate on substantive issues with the CMEA, officially because EC leaders feel that CMEA organs are without power on most of the matters proposed for negotiations in the CMEA draft agreement. They probably believe that, but in addition, they believe that negotiations with CMEA would cause a recentralization of power in the organization.

But that seems an excessively optimistic view of the influence of the EC over the internal distribution of power in CMEA. The main forces pressuring the CMEA countries towards a centralization of some of their economic decisions lie within the CMEA or in the massive upheavals on world markets which affect CMEA. In addition the EC has exerted some influence on the distribution of power in CMEA, not through any of its decisions on negotiations, but through the enlargement to nine members, and the successes of the CCP and CAP. *In other words, it is the mere existence of an enlarged EC and the success of several of its policies affecting trade with CMEA which serve as the incentive for the creation of a meaningful common socialist commercial policy and the distribution of power in CMEA which that implies.*

Just as the Soviets earlier misjudged the strength of forces pushing towards recentralization of economic decision-making in Western Europe, the EC seems now to be misjudging similar forces pushing towards recentralization of economic decision-making in Eastern Europe. If this analysis is correct then time should erode this misunderstanding on the part of the EC policy-makers, and as that occurs the perceived political cost of negotiations will fall substantially. Negotiations will come to be viewed as a symbol of EC success with relatively small political ramifications for Soviet-East European relations.

Still, while the perceived political costs for the EC of negotiations may fall, the perceived economic benefits at present are small and relatively uncertain. The EC faces no well-defined common socialist commercial policy as of yet, nor does it face a well-defined common industrial policy, which would be the type of policy of most import for EC goods. On the other hand, there is a strong *de facto* protection of CMEA domestic industry against foreign competition and if the EC could use the CCP and CAP as levers to weaken some of those barriers it could possibly expect large increases in exports of manufactured goods in exchange for more primary products, simple manufactured goods and possibly agricultural products. Now of course these are *national*, not *supranational*, barriers in CMEA which exist in intra-CMEA trade (to a lesser extent) as well as in East-West trade; and EC negotiations with individual national authorities could remove those barriers. That is, the CMEA has not achieved the planning equivalent of a common market. But it may be the CMEA already seems to have enough internal cohesion to reject the notion of direct EC-CMEA member-country negotiations without an umbrella agreement between the EC and CMEA.

Aside from the political and economic considerations surrounding CMEA-EC negotiations, one must remember that it is not at all apparent that trade agreements really mean anything in trade among individual nations, let alone in trade among groups of nations. While I know of no comprehensive study of the impact of trade agreements on trade flows, purely non-scientific impressionistic evidence would suggest that trade agreements serve to ratify what has already begun to transpire; that is, they are almost in the nature of a ceremony. Typically the Soviets seem to place much more weight on their conclusion than the western partners. There is, of course, more than mere ceremony involved here. If the trade agreements involve specific quantities or types of goods then the Soviets will build those preferences into their decisions on the geographic structure of trade through the Treaty and Legal Administration and the Geographic Administrations of the Ministry of Foreign Trade.<sup>53a</sup>

Also on the western side the trade agreement may serve to provide western exporters and importers with more information on possibilities for trade, which in turn may affect trade flows. But potential effects on trade flowing directly from these are uncertain and probably not terribly large. On the other hand there seem few potentially objectionable consequences of inter-national trade agreements, and presumably this would also apply to inter-economic union trade agreements.

All of these considerations seem to suggest that if CMEA continues to push for CMEA-EC negotiations, they will most likely finally get them. The political costs to the EC seem small and so do the economic benefits. But the Soviets may make it clear that any EC-individual CMEA member-state negotiations must occur under a CMEA-EC umbrella; and in fact the Soviets may succeed in bringing some trade issues up to the level of CMEA itself (for example cooperation agreements on large fuel and primary product projects).

If and when the negotiations do occur they will be extremely complex because they involve three major unresolved issues: the distribution of power in the CMEA, the distribution of power in the EC, and relations between the EC and CMEA. If one looks for example at the CMEA draft agreement—which seems a reasonable agenda for the talks—it is apparent that much of the negotiating time on particular issues may involve negotiations *within* the CMEA and EC on just who has the power to give concessions. Quotas in the EC are primarily the business of member-states; in CMEA they are totally member-state business. Yet the CMEA draft agreement proposes discussions about trade barriers. If the discussions became very specific, then they would either have to be bilateral (between member-states on both sides) or else the entire history of autonomy in this area in both organizations would have to be reversed. Some issues such as market disruption clauses would seem potentially far less controversial and in fact appropriately handled at the EC-CMEA level.

A CMEA-EC Joint Commission along traditional lines would be a particularly sticky issue since there are many bilateral joint commissions now in existence, and they could hardly be expected to relinquish all of their powers. But the CMEA-EC Commission might

<sup>53a</sup> For a discussion of this process see my "Most Favored Nation Treatment in Trade under Central Planning," *Slavic Review* (forthcoming).

limit itself to discussing pan-European projects too large to be considered by individual bilateral commissions.

Thus while negotiations seem quite likely, their content and outcome are difficult to predict. What seems probable is an agreement which for the most part sets a framework for continued negotiations between individual member-states or between individual CMEA states and the EC. The interesting question is if decisions on some trade matters in the CMEA will be centralized so that negotiations between the CMEA and individual EC member-states will make sense. It seems doubtful at this point. Undoubtedly the CAP will be discussed at the EC-CMEA level, but it seems doubtful that much will be resolved unless Eastern Europe succeeds in linking CAP to Soviet energy supplies or improved access to CMEA markets. Both are possible, but CMEA is still a relatively unimportant set of trade partners for the EC, and major concessions on CAP seem highly improbable.

If the agreement really affects trade, it will probably be on very big questions concerning cooperation probably in areas such as fuels, primary products, transportation, communications, energy, or the environment.

### *The Implications for U.S. Relations With the EC and CMEA*

It seems clear that the successful conclusion of an EC-CMEA agreement of the type we have outlined here will have little impact on U.S. relations with either the EC or CMEA. In the large issues of all-European cooperation where the agreements may have some influence on trade, most of those are either not related to trade outside of Europe (transport, the environment, communications, or some forms of energy such as an all-European electricity grid), and the others have little importance for U.S. trade with those areas.

As Table 2 shows, U.S. exports to the EC, like U.S. exports to the world, concentrate in agriculture and food products, and in machinery and equipment. It seems unlikely that the EC-CMEA agreement will result in the EC discriminating in its Common Agriculture Policy in favor of CMEA against the U.S., so the impact on that portion of trade will be small.

TABLE 2.—U.S. EXPORTS, 1974 (PERCENT OF TOTAL)

Standard industrial classification category	Exports to	
	EEC 9	World
0 Food and live animals.....	13.6	14.4
1 Beverages and tobacco.....	2.1	1.3
2 Crude materials, excluding fuels.....	16.0	11.3
3 Mineral fuels, lubricants, and related materials.....	3.4	3.5
4 Animal and vegetable oils and fats.....	1.1	1.5
5 Chemicals.....	10.3	9.1
6 Manufactured goods classified chiefly by materials.....	10.9	11.5
7 Machinery and transport equipment.....	33.3	39.4
8 Miscellaneous manufactured goods.....	7.0	5.5
9 Goods not elsewhere classified.....	1.1	2.7

Source: U.S. Department of Commerce, Bureau of the Census, U.S. Exports: World Area by Commodity Groups, FT 455. Annual 1974.

In machinery and equipment there will surely be joint commissions set up, many meetings, and so on; but none of these should have a major impact on the comparative advantage the U.S. has in the pro-

duction and export of many types of machinery, such as computers, office machinery, telecommunications equipment, and aircraft. The only potential effect could be that the CMEA negotiators would agree to try harder to discriminate in favor of EC machinery exporters, but that would only have an impact in those areas where the EC export products are very similar to U.S. products. The impact there could be important but it would take a very detailed study of commodity groups to see how important. But the crucial point here is that such a commitment by CMEA planners to discriminate in favor of EC exporters would probably only come if the EC would agree to discriminate in favor of CMEA machinery and equipment. That might prove a high cost, hence agreement in that area seems unlikely in the near future.

In primary products and fuels, where the EC-CMEA agreement might have some impact, U.S. exports are not substantial, therefore those interests would not be affected. On the import side the only possible impact is that should the U.S. Government revive an interest in large cooperative projects concerning energy in the USSR, they could now find a competitor in the EC as a whole. Most of these projects involve Soviet commitments of capital, labor, and materials, and there must be some limit to how many commitments the Soviet Union can contemplate at one time, thus it is not inconceivable that the U.S. and EC could find themselves competing in the Soviet Union contracts on enormous projects involving fuels and primary products.

In conclusion, from an economic point of view it would seem that any foreseeable CMEA-EC agreement would have no major consequences for U.S. relations with either group. The agreement will probably be long in coming; there are too many impediments to be removed to expect any early settlement. Also, when it does come, the issues on which CMEA and the EC have mutual interests conducive to agreement are for the most part in areas which are relatively unimportant to U.S.-EC and U.S.-CMEA relations. There could be some effects on discrimination against U.S. exporters and some more concerted competition on big projects; but neither of those seems at present to loom as a major consideration.

What will probably be much more important for these agreements is their implications for political trends in Europe and political relations between Eastern Europe, Western Europe and the U.S. The Soviets have an image for Western Europe just as they have one for CMEA, and agreements such as these are probably an important part of the realization of that image. It is probably this image, which spans both politics and economics, which should be the subject of further research.

## I. INTRODUCTION

This paper presents summary measures of the post-1965 economic performance of six countries of Eastern Europe: Bulgaria, Czechoslovakia, East Germany, Hungary, Poland, and Romania. This will be done primarily by reference to tables showing the structure of economic activity as regards both the origin and the final uses of product, the allocation of resources to various sectors of production, the productivities of labor and capital, and the rates of growth of output and inputs.

Economic performance, of course, is the outcome of complex interaction of personal motivations of employees, managers, consumers, political party and government officials, as well as of the availability of resources—labor, capital, and land, state policy regarding priorities for production and consumption, the institutional framework determining the rules of the game, participation in world trade, applications of science and technology, such exogenous factors as the weather and international politics, and many other considerations. Essays on particular national economies in the present volume examine many aspects of this complex interaction. The present paper has the more limited aim of presenting the outcome of economic activity by conventional summary indicators, but some reflections on the economic milieu and problems will be offered as well.

Part II of this paper describes the outcome of economic activity in terms of the changing percentage composition of sectors of origin and final uses in national income aggregates (both the gross value added, GNP or GDP, and the net material product, NMP concepts) and the changing patterns of labor and capital inputs. Structural changes reflect diverse rates of growth of the corresponding economic categories; Part III provides such growth measures. Part IV presents some summary indicators of labor and capital productivities. Part V examines briefly some current problems and future perspectives

confronting the economies. Part VI provides a brief summary of the findings of this paper. The reader may wish to refer to it first and then to study the details in the other parts.

Although our tables represent implicitly the outcomes of the manifold interactions of causative factors, such tables cannot fully comprehend the performance of the economies. Important qualitative aspects of performance are often poorly reflected in the conventional performance measures.

Intertemporal and international statistical comparisons by means of index numbers are inevitably relative to their bases of valuation and to the methodology and concepts used to make the comparisons. At various points in this paper we shall note striking statistical anomalies in order to emphasize such relativities. Here we may illustrate the problem by citing two instances drawn from Tables 4 and 14. According to official Hungarian versions of the composition of the net material product (NMP) national income, Table 4, the share of industry in 1965 in the total NMP was originally shown as 66.9 percent in "comparable prices" and subsequently was revised downward for the same 1965 year to 41.6 percent in 1968 comparable prices. (In 1965 current prices the 1965 share was 58.1 percent). The share of trade in 1965 "rose" from 0.6 percent in the original version to 13.5 percent in the revised; agriculture's share increased from 16.4 percent to 24 percent. The other citation refers to the index for the trade sector in Romania's NMP national income over the 1965-1970 period (see Table 14): 1965=100, 1966=88, 1967=76, 1968=77, 1969=60, 1970=24. For subsequent years, the index has not been published in Romanian sources.<sup>1</sup>

These citations are not intended to denigrate the official national income statistics of Hungary or Romania; relativities with respect to bases of valuation, concepts, and methodology abound in statistics of many other countries, though perhaps not often to such extremes as noted above. However, at least one observation is warranted here. It is directed towards those who would use such statistics without critical examination of the effect of linkages of component segments of indexes calculated according to diverse methodologies and weight regimens, when the users juxtapose such linked output indexes to labor and capital input indexes in order to calculate factor productivities, elasticities of substitution between capital and labor, and rates of technical change. Abstraction, or model building, to explain the past and to prognosticate is a commendable exercise; it surely has didactic value; but the explanations of the past and the prognoses based on sophisticated fittings of various production functions to empirical observations that may come in assorted and mixed specifications should be treated with caution.

The labor input series into various branches of production would appear to be more consistent than the available output indexes and the capital input series. But one must reckon with boundary changes in regard to branches and their related input and output series. Sometimes

<sup>1</sup> A revised index appears in the CEMA yearbooks of recent years showing growth of the Romanian trade sector. The CEMA 1976 yearbook shows the following trend: 1960=41, 1965=70, 1970=100, and 1975=151; however, the total NMP national income and its major sectors have not been revised retrospectively in the CEMA source. It is not clear whether the post-1970 national income total for Romania in both its own yearbook and in CEMA's was affected by possibly a new trade index component or whether the accounting proceeds along old lines with the anomaly not apparent by non-publication of indexes for trade and "other" sectors.

the boundary changes are not applied retrospectively to yield consistent coverage over time. The reclassification of non-material (or so-called non-productive) transportation and communication into the material sphere is a case in point. Another instance occurs where employees of non-productive administrative agencies are by fiat added to a material sector's employment when government branch managements devolve into enterprise branch associations. Fixed capital series, that may be presumed to be at constant prices, in fact may fail to meet this expectation over long periods. (Bulgaria is a notable example here.) The conclusion to be drawn from these remarks is simply that overly sophisticated analyses with unadjusted input and output statistics may be seriously misleading.

Data imperfections notwithstanding, intertemporal and international comparisons are being made, and when taken as rough measures, they provide useful perspective on economic development. Our aim here is to contribute to such an appreciation of economic change in Eastern Europe by presenting both our independently calculated GNP estimates and the national official statistics in the truncated net material product (NMP) national income concept and by reviewing the composition of employment of labor and capital at selected years over the 1965-1975 period. Rates of growth of outputs, inputs, and factor productivities will be shown implicitly in indexes and explicitly as averages over five and ten year intervals.

The growth formula fitted by least squares to the empirical data is the familiar compound interest equation:  $I_n = I_0(1+r)^n$ , where  $I_0$  is the initial observation,  $r$  is the annual rate of growth,  $n$  is the number of years, and  $I_n$  is the terminal observation. The determined rate of growth is an average, and in common with all averages it hides the interesting detail that the annual observations provide. The caution to be noted here is that a seeming contradiction may emerge, say, when the rates over a ten-year span are computed for the two subperiods of five years and for the period as a whole. Not so rarely as one might expect, the rate for the period as a whole may be lower than each of the rates of the component subperiods. When such a situation is seen, it does not follow that the computations were faulty.

It may be a matter of taste whether to prefer the rate determined by the least squares fit, or the rate as the  $n$ th root of the overall growth in the period of  $n$  years, or as a simple arithmetic average of the rates expressed as annual increments over the period. The choice will depend on the purpose, and so long as the series of annual observations are given, the various alternative rates may be readily calculated.

A guiding principle in making comparisons is to observe symmetry among countries and intertemporally for a given country. Here the most obvious, and perhaps unnecessary, caution is to beware of making comparisons between GNP or GDP (gross domestic product) measures on the one hand and NMP (net material product) national income measures on the other. The NMP concept excludes government services and some other services for the population from national income; GNP and GDP include them. The NMP concept at one time excluded passenger transportation and communications services for households and "non-material" sector users. Currently only Czechoslovakia and the Soviet Union follow this convention; other CEMA countries of Eastern Europe have at various times enlarged the

"material product" sphere to include all transportation and communications, and, moreover, as consequences of organizational reforms, have shifted some "non-material" services (and their employees) into the material product sphere measures. When such changes are made, but the antecedent economic indexes are not retrospectively adjusted to the new coverage, the expansion in coverage may manifest itself as "growth". Hence some circumspection is required on the part of analysts who seek precision in comparability. Usually the national statistical sources signalize changes in coverage and price regimens pertaining to their serial economic measures, but commonly they do not retrospectively adjust the measures to insure comparability over time.

The caution here is for the analyst to adjust the data series himself, or, at a minimum, to advise his readers of the discontinuities and their likely consequences for the conclusions drawn from the unadjusted series. For what may be interpreted as growth or deceleration of growth, or absolute decline in an index may not reflect real trends so much as the discontinuities mentioned above, as well as the methodology for the calculation of measures of growth. In the instance of the NMP index of trade for Romania that was cited above, a fall in the index from 100 in 1965 to 24 in 1970 would appear to have substantial consequences for the overall NMP national income index. Surely trade services did not decline in the sense one ordinarily visualizes such services. The anomalous behavior of the official index no doubt reflects the official definition of the trade sector to include some consequences in connection with price equalization procedures in foreign and/or domestic trade.<sup>2</sup>

In order to facilitate intertemporal and international comparisons we present our independently calculated GNP measures as well as the official NMP national income statistics for the East European countries. In our GNP measures we have adjusted established domestic market valuations, which embody various distortions on the account of unsymmetric incidence of turnover taxes, profits, and subsidies, in order to approximate factor cost weights for our sector of origin indexes of GNP. The resulting GNP measures should provide insights into the structure, performance, and comparability of the economies that the NMP measures alone cannot offer.<sup>3</sup>

## II. STRUCTURAL CHANGES IN ECONOMIC ACTIVITY

In Tables 2-9 we examine the structure of economic activity as reflected in the composition of GNP, NMP, employment and fixed capital. Table 1 on population and Table 10 on dollar values of the national products provide some bases for perspective on the economies of Eastern Europe in international settings.

<sup>2</sup> Hungarian national income official figures for NMP produced in 1955 show a total NMP of 94.3 billion forints, of which domestic trade contributed a positive net product of 11.9 billion forints and foreign trade a negative net product of 8.8 billion forints on external trade that was about balanced in foreign currencies, but showed a huge loss in domestic forints (see Alton and Associates, "Hungarian National Income and Product in 1955," p. 92, citing the official Hungarian statistical yearbook, *Statistikai évkönyv*, 1949/55, p. 39). Possibly in the case of Romania, growing losses on price equalization over a period of years caused the strange behavior of the NMP index of trade.

<sup>3</sup> Details on our methodology and sources are given in the "Occasional Papers" (OPs) of the Research Project on National Income in East Central Europe; see the listing in the bibliography at the end of the paper. OPs numbers 48 and 50 as updated for the present article provide summary information on our indexes.

*Population: Numbers, Indexes, and Rates of Growth*

The population data in Table 1 show a total population of 106.88 million for the six countries for mid-year 1976. For comparison, the mid-year 1975 populations in millions were as follows: six countries of Eastern Europe—106.2; United States—213.6; USSR—254.5; France (1974)—52.5; West Germany (1974)—62.1; and Italy (1974)—55.4.<sup>4</sup> Thus, in terms of population the six countries represent about 50 percent of the level of the United States and 42 percent of that of the USSR. Although individually the countries are relatively small, taken together they represent an important aggregate in terms of population and economic potential.

<sup>1</sup> Estimate.

Sources: Statistical yearbooks and official plan fulfillment reports.

Population growth in the six East European countries as shown by comparisons of increases over the 1955-1965 period versus the increases over 1965-1975 has slackened in three countries, declined at a lesser rate in East Germany, and increased in Hungary and Romania. For each country, the percentage increments in the corresponding periods, 1955-1965 versus 1965-1975, calculated from national statistical yearbooks, were as follows: Bulgaria, 10.9 to 6.4; Czechoslovakia, 10.8 to 4.5; East Germany, minus 5.2 to minus 1.0; Hungary, 3.3 to 3.9; Poland, 15.5 to 8.0; and Romania (1956-1966 vs. 1966-1976), 9.2 to 12.1. Thus Romania alone has more than maintained its substantial momentum, but one may expect from the shape of the

<sup>4</sup> U.S. and U.S.S.R. data: U.S. Congress Joint Economic Committee, "Soviet Economy in a New Perspective," October 1976, p. x; OECD countries: OECD, "Labor Force Statistics," 1963-1974, p. 15.

Romanian "population tree" that some slackening of the tempo may be expected in the future. There was a sharp reduction in the number of annual new cohorts from 1960 to 1966, but a state policy reversal on free abortions resulted in a 1968 cohort about twice as large as that of 1966. Subsequently a new "pinched waist" formation appeared in the population tree, suggesting that Romanian families were again restraining births, but not so sharply as around 1966.

The labor force of the 1970s will reflect births of the 1950s, but the more recent births figure in the consumption side of the national product, and they will provide the new entrants to the labor force in the 1980s and subsequently. The average annual rates of increase of population shown by the United Nations "Statistical Yearbook, 1975," for the 1970-74 period for the six countries of Eastern Europe and selected other countries were as follows: Bulgaria—0.6; Czechoslovakia—0.6; East Germany—(-) 0.2; Hungary—0.3; Poland—0.9; Romania—0.9; United States—0.8; West Germany—0.6; Italy—0.8; Spain—1.1; and the United Kingdom of Great Britain and Northern Ireland—0.2. There is relatively little difference between Eastern Europe as a whole and the average for the other indicated countries. If present trends continue, then Eastern Europe will be facing increasing labor scarcities. Labor shortages already are manifest in East Germany, which has the continued distinction of a declining population, in Czechoslovakia, and in Hungary. Even Bulgaria is concerned over labor shortages, and Poland and Romania are expected to face shortages a decade or so hence.

The agricultural population in Eastern Europe still constitutes a substantial reserve for transfers to other sectors despite its steeply declining share in the total of economically active population (see Table 6). It is against this background of relative labor scarcity compared to the earlier post-World War II years that such great emphasis is being placed upon more rapid technological progress and capital investment to make possible increased labor productivity.

#### *Composition of National Product by Sectors of Origin*

Tables 2, 3 and 4 indicate the changing composition of national product by industrial sector over the 1965-1975 period. Tables 2 and 3 are in the GNP or GDP concept, and Table 4 in NMP national income concept.

The structural changes in GNP in constant prices (Table 2) reflect the continued emphasis upon industry as the prime sector fostering economic growth.<sup>5</sup> Agriculture, however, though still showing a declining sectoral share, has been receiving more favorable treatment in pricing of outputs and in allocation of inputs. Nonetheless, agriculture's share in total employment and in national product may be expected to decline further in future years, barring unforeseen, more sharply favorable policies on prices and other incentives to farmers. Construction did not show great changes, generally holding its share or increasing modestly. Exceptions here were East Germany and Poland, with substantial increases, and Romania, which showed an increase from 1965 to 1970, followed by a decline to 1975. Industry showed a

<sup>5</sup> The sectoral shares shown in Table 2 of the present article differ somewhat from the composition shown in my article in the 1974 JEC Compendium, partly because of revision of sectoral weights and the use of a more recent weight-base year.

leveling-off trend in sectoral shares in Bulgaria, Czechoslovakia, East Germany and Hungary, but increased its shares substantially in Poland and Romania.

Source: Derived from GNP measures shown in table 13.

The spread in the shares of industry among the six countries in total GNP diminished significantly over the 1965-1975 period. With rising levels of economic development one may well expect industry's share

eventually to decline as the service sectors gain importance. East Germany and Czechoslovakia stand at the top of the list in the share of industry (42 percent) in GNP. Romania, Bulgaria, Hungary and Poland, in declining order still have agricultural shares in 1975 in the 29 to 19 percent bracket. East Germany has the lowest agricultural share in 1975 (13.5 percent of GNP).

Table 3 shows in current prices the industrial composition of GDP for non-CEMA countries of Europe and the United States. West Germany ranked first in the share of industry (43 percent), a share almost identical to that of East Germany and Czechoslovakia. At this juncture one should note that comparisons of this kind are extremely rough, and the shares in the various countries are strongly affected by the bases of valuation, sectoral boundaries, and methodology of calculation, which may differ among countries. Despite such differences, Table 3 suggests that Eastern Europe may be expected to decrease further the share of agriculture and to increase the share for services as the economies continue to develop. The very low shares for agriculture (3 to 5 percent) for the more developed countries shown in Table 3 (USA, UK, West Germany, France and Japan) are unlikely to be reached in Eastern Europe in the short run.

TABLE 3.—NON-CEMA COUNTRIES: COMPOSITION OF GDP BY INDUSTRIAL ORIGIN, 1973 OR 1974

Note: The GDP is expressed in current producers' values, and its composition by industrial activity is in terms of the U.N. SNA system. In some cases the percentages do not add up to 100 because of statistical discrepancies and because import duties are in many cases not included in the reported industrial group but do enter the total GDP. Agriculture and forestry include hunting and fishing. Industry includes mining, quarrying, manufacturing, electricity, gas, and water.

Table 4 showing the shares of material product sectors in the NMP (net material product) national income is not directly comparable to Tables 2 and 3, not only because of the narrower product concept but also because of different bases of valuation. This lack of comparability applies within Table 4 itself, both for a single country and among countries primarily because of differences in relative valuation among sectors. But changes in coverage of the NMP concept also affect the comparisons. At various points in time all of the countries except Czechoslovakia have transferred passenger transportation and communications serving households and non-material sectors of production from the non-material to the material product sphere. In the 1965-1976 period only Bulgaria and Romania made this transfer. There have also been other such transfers enlarging the material product sphere, and the footnotes and introductory text to the national income chapters of the national statistical yearbooks make clear the lack of comparability over time that these transfers cause. We have not attempted to adjust

the published figures to achieve comparability, and indeed the task might well require more information than is given in the readily available statistical compilations.

<sup>1</sup> In Jan. 1, 1962, prices through 1971. In Jan. 1, 1971, prices since 1971.

<sup>2</sup> In current prices. 1970 and later years reflect changes in coverage to include passenger transportation and the communications services formerly excluded from material product, and also some services formerly excluded from industry and agriculture.

<sup>3</sup> In Apr. 24, 1960, prices.

<sup>4</sup> In Jan. 1, 1967, prices.

<sup>5</sup> In current prices.

<sup>6</sup> Apr. 24, 1960, prices.

<sup>7</sup> Jan. 1, 1967, prices.

<sup>8</sup> In comparable prices.

<sup>9</sup> In 1968 comparable prices. "Other" includes water economy.

<sup>10</sup> In constant 1961 prices. Domestic NMP only.

<sup>11</sup> In constant 1965 prices. Domestic NMP only.

<sup>12</sup> In current prices. Domestic NMP only.

<sup>13</sup> In constant 1971 prices. Total NMP.

<sup>14</sup> In current prices; 1970 figures reflect changes in coverage to include passenger transportation and the communications services formerly excluded from national product, and also some services formerly excluded from industry and agriculture.

<sup>15</sup> Official breakdown is not available. According to tabulation provided by the CEMA statistical office for NMP in current prices, the share of trade was 7.5 percent in 1965, 3.5 percent in 1970, and 10.6 percent in 1976. The share of "Other" sector was 1.5 percent in 1965, 1.9 percent in 1970, and 1.7 percent in 1976 (see "Statisticheskiy Ezhegodnik Stran-Chlenov Soveta Ekonomicheskoi Vzaïmopomoshchi, 1976," p. 44).

Note: See appendix, notes to tables 4, 5, 14, 15, 16, etc.

We have included breakdowns of NMP by industrial sector for given years for several countries in more than one set of prices in order to illustrate the oftentimes extreme shifts that changes in valuation bring about. The footnotes to the table indicate the price bases underlying these changes. Perhaps most striking is the "deindustrialization" within a single year. In Bulgaria, for example, in 1965 industry accounted for 49 percent of NMP in 1962 prices, but only 45 percent in current prices. A comparable "decline" in Czechoslovakia in 1966, from 67 to 62 percent, resulted from valuations in 1960 and 1967 prices, respectively. Most striking was the change in the share of industry in Hungary in 1965: from 67 to 58 to 42 percent in the transition to more recent price bases. Romania's two different shares in 1970 for various sectors reflect boundary changes for overall NMP and for component sectors; "non-productive" passenger transportation and communications were made "productive" or "material," and some other services were annexed to agriculture and industry. It would appear that the growth of NMP reflected in chain linked indexes would be affected by the changes in price bases and production boundaries. Thus, analysis of economic growth—acceleration or deceleration—should consider what is "real" and what is a consequence of changes in relative valuation and coverage. Labor inputs are not subject to this problem, although changes in sectoral boundaries, and changes in the length of the work year in days or hours, as well as other factors bearing upon the consistency of the labor input series, must be considered. Still, one should ponder the significance of labor productivity indexes over long periods where the output index may behave variously according to relative valuations underlying the links in the output index, whereas the labor input series is not so seriously affected, or can be made more or less consistent in terms of hours worked.

A close reading of Table 4 should identify by means of the footnotes the years that are valued in a single set of prices and thus provide an impression of the structural changes occurring over time. Thus for Bulgaria, the proportions in 1965 and 1970 based on 1962 prices are indicated by footnote 1. In this interval industry's share grew from 49 to 55 percent of the NMP national income; agriculture's share fell from 28 to 18 percent. The "real" changes in shares from 1970 to 1975 cannot be inferred from Table 4 unless one assumes no change effected by valuations in current prices of the two years. Shares for 1975 in constant prices were not available.

In Czechoslovakia the sectoral shares based on 1967 prices for 1965, 1970 and 1975 showed a small decline for industry from around 66 percent to 63 percent; for agriculture there was a decline from 12 to 9 percent. The picture for East Germany in comparable prices shows industry gaining three percentage points and agriculture and forestry easing about 4 percentage points over the period of 1965–1975. In Hungary, in 1968 comparable prices, industry's share rose slightly, from 42 to 45 percent; agriculture fell from 24 to 15 percent. In Poland, over 1965–1975, in constant 1971 prices, industry's share rose from 45 to 52 percent; agriculture and forestry's declined from 26 to 13. The structure of Romania's NMP national income shown in Table 4 is in current prices of each indicated year; constant price structure over the 1965–1975 period was not available. The general impression, however, is that industry gained in share and agriculture dropped steeply.

Four further comments on Table 4 are warranted. First, the shares exhibited in the table are in market prices and reflect the incidence of turnover taxes, profits and subsidies. These distortions from factor cost on balance favor industry, where the turnover taxes and profits, as forms of "socialist accumulation" (saving or revenue to finance investment and other social objectives) in general are realized in industrial selling prices. Second, because NMP national income excludes "non-productive" services (government, etc.), but GNP does not, the percentage shares of net material product originating in the total NMP for industry and other material sectors would be larger than corresponding shares in GNP, where allocations have to be made to the sectors excluded from NMP. The fact that GNP includes capital consumption allowances whereas NMP excludes them of course should be taken into account here, but the consequences of this consideration would have to be sorted out in terms of the distribution of fixed assets and depreciation rates. Third, the NMP concept refers to gross output less material costs; purchases from "non-material" sectors appear as net material product of the buying sector. Although the total of such purchases is not large, if some sector, say industry, accounts for a disproportionate part of the total, then some distortion would follow as compared to the conventional notion of value added. Finally, fourth, and most important, the bases of valuation underlying Table 2 differ from those of Table 4; Table 2 represents approximations to factor cost; Table 4 is in established prices. The principal outcome of this difference would be more symmetric valuations in Table 2.

Economic statisticians in Eastern Europe are aware of the consequences that alternative bases of valuation may have upon the structure of national income (material product concept). Thus, in the instance of Poland,<sup>6</sup> the Polish Main Statistical Office (GUS) calculated the composition of gross national income (net material product plus depreciation) in realized, or established current prices on the one hand, and in three alternative bases of current valuation: variants A, B and C. Variant A was calculated in prices adjusted by subtracting from the value of net production in current realized prices the taxes (including turnover taxes, income taxes in cooperatives and the private sector, and land tax in agriculture) and positive budget differences (a levy very much like the turnover tax) and by adding subsidies and negative budget differences (which in effect are a form of subsidy). The intent here was to make the adjusted values of net product in particular sectors and branches of the economy more proportional to the corresponding outlays of social labor (live and that embodied in objects). Variant B was calculated in adjusted prices reflecting the outlays on live labor (*pracy żywej*) in the various sectors and branches. These outlays comprise wages and other payments for labor, social security contributions, and net incomes of units in the private sector. Agricultural labor cost was taken as the sum of wages and social security contributions in state farms and net incomes of production cooperatives and private farms.

In the calculations under variant B a limiting constraint was made that the total value of consumption from personal incomes would be

<sup>6</sup> See Poland, Główny urząd statystyczny (GUS), *Rocznik dochodu narodowego, 1971*, "Aneks, Dochód narodowy w cenach umownych" (Annex, National Income in Adjusted Prices), p. 214 ff.

the same in both the actually effective realized prices and in the adjusted variant B prices. Variant C calculations were made along the lines of variant B but with further adjustment to reflect the contribution of fixed capital in various sectors and branches, taking this contribution as equal to one-sixth of reproduction cost (*wartosci odtworzeniowej*) of the fixed capital, a ratio corresponding to a six-year period of recoupment (*okres zwrota*), assumed to be the average for the economy as a whole. Also in variant C, the constraint that the value of consumption from personal incomes should be the same in the actually realized prices as in adjusted prices was not introduced. There were other estimative and procedural details in the alternative calculations, but the above simplified description suffices for the illustrative purposes here. The Polish state statistical office stressed most emphatically that the alternative calculations were not to be considered other than rough estimates and cannot be interpreted as pointing to a need for changes in the existing system of realized prices nor are these alternative calculations to be taken to represent economically justified sets of prices of realization.

In effect, these provisional recalculations by the Polish statistical office follow roughly along the lines of our own earlier calculations of the structure of national product at prices approximating factor cost.<sup>7</sup> The tabulation below shows the results of the GUS calculations of gross domestic national income for 1967 in current prices in four alternative bases of valuation for sectors of origin of product. Gross national income here means that capital consumption allowances were not subtracted along with other material costs from gross output to arrive at the aggregate. The gross national income therefore is the net (NMP) national income plus depreciation of fixed assets in the material sphere of production.

## STRUCTURE OF GROSS NATIONAL INCOME, 1967

(In current prices)

	Realized prices	Var. A	Var. B	Var. C
Total.....	100	100	100	100
Of which:				
Industry.....	51	45	39	41
Construction.....	9	11	13	8
Agriculture.....	19	21	28	27
Transport and communications.....	8	9	8	13
Trade.....	9	10	7	6

In all the variants (A, B and C), industry's share declines very substantially while that of agriculture increases. Variant C comes closest to our notion of structure at factor cost. In this variant, as compared to the structure in realized prices, in percentages of the total, industry declines from 51 to 41 (i.e. by one-fifth); agriculture rises from 19 to 27 (by about one-half), and transport and communications rise from 8 to 13 (about five-eighths); trade declines by about one-third; and construction stays roughly unchanged.

The composition of gross national income distributed remains practically unchanged in variants A, B and C as compared to its

<sup>7</sup> See the bibliography for Alton and Associates, "Polish National Income and Product in 1954, 1955 and 1956," and our more recent Occasional Papers on trends and structure of Polish economic activity.

structure in realized prices.<sup>8</sup> Although the major final use components expressed as shares are relatively unchanged in the four variants, this does not mean that subcomponents will all duplicate this stability. This is clear with respect to the branch composition of industry in the four variants (see below). We would expect some substantial changes for shares of subcomponents of final uses when displayed in the four variants within the major categories of personal consumption, collective consumption, and gross investment in the gross national material income distributed. Under personal consumption there should appear repercussion of the declining shares of textiles and food (see below). Within collective consumption and gross investment under the current prices of realization some subcomponents may be relatively subsidized vis-a-vis others. Allocations of product to favored investment uses and to military procurement in current prices of realization may appear as relatively low shares compared to what they would be at approximations to factor cost.

The GUS calculations by four alternative sets of valuations for sectoral structure of production given above cannot show very substantial changes within the industrial sector. Such changes were tabulated by GUS for branches of industry. Perhaps the most significant changes evident in the juxtaposition of 1967 shares within industry as a whole taken as 100 in each variant, were the following, showing first the branch percentage share at actually realized prices and second the corresponding branch share in variant C. Fuels, 10.5—14.9; ferrous metallurgy, 4.9—9.5; textiles, 10.8—7.2; food, 18.0—9.9. For other branches there were smaller variations, up and down. The major changes no doubt reflect the significant influence of the returns to capital and the incidence of turnover tax and other forms of accumulation of financial means to finance investment and other state purposes. Such financial transfers would appear to impinge heavily in favor of the textiles and food shares in the actually realized prices, and the adjustment in variant C accordingly reduces the shares of these branches.

We have not seen more recent official recalculations of the structure of economic activity, although economic policy and planning require a more realistic view of the allocation of factors of production (labor, capital and land) than is afforded by the statistics in actually realized prices. We should note that the composition of gross (material) national income under variants A, B and C still cannot be simply juxtaposed to the composition of GNP or GDP; the latter aggregates include so-called nonproductive services that are excluded from gross (material sector) national income (*dochod narodowy brutto*) used in the GUS recalculations. In addition to this difference in coverage, there are differences in valuation and methodology between the GUS concept and GNP as we calculate it.

### *Composition of National Product by End Uses*

As in the case of the composition of national product by sectors of production considered above, we shall show here the distribution

<sup>8</sup> It is not clear from the brief notes to the GUS estimates whether the ratios along rows in variants A, B, and C reflect the impact of differential pricing evident in the established price version of the I-O table as between consumption (heavily burdened by turnover taxes) and net investment, although the row totals reflecting adjustments toward factor cost would differ from what they were at realized prices.

of national product to final uses in both the gross value added concept (GDP) and in the less comprehensive net material product (NMP) national income concept.

We shall consider first the GDP use composition in current prices in 1974 for Poland and Hungary. Dr. Eugenia Krzeczowska of the Polish Institute for Statistical-Economic Research in the Main Statistical Office (Główny Urząd Statystyczny—GUS) has expanded the 1974 Polish NMP national income produced to the United Nations Standard National Accounts GDP.<sup>9</sup> She did this by starting with the material product system (MPS) gross national income produced (NMP plus capital consumption allowances), subtracting therefrom the nonmaterial services incorporated in the NMP aggregate, and adding next the net production of nonmaterial services, the depreciation in the nonmaterial sphere, and imputed rent and profits in housing in order to place this subsidized element in the Polish economy on a more comparable footing to Western accounting.

The result in current 1974 zlotys was 1,503 billion zlotys of gross domestic product produced. We adjusted this total to take account of the difference in Polish official national income statistics between national income produced and national income consumed.<sup>10</sup> This difference consists of the surplus of imports over exports and the losses of national income produced. The combined value of the two indicated components of the difference, 90.3 billion zlotys, was broken down into losses (19.8 billion zlotys, estimated at 1.64 percent of national income produced, the ratio in 1974 for Czechoslovakia as shown in *Statistická ročenka CSSR 1976*, p. 152) and the estimated import surplus (110.1 billion zlotys, obtained by adding the losses to the 90.3 billion zlotys of the difference between the distributed and produced NMP national income totals). Gross investment in 1974 was estimated as the sum of net investment ("accumulation," 467.3 billion zlotys) plus depreciation in the material sphere (117.3 billion zlotys, as shown in *RS 1976* p. 71) plus depreciation in the nonmaterial sphere (30.5 billion zlotys, as estimated by Krzeczowska), or a total of 615.1 billion zlotys. This total represents 38.6 percent of the 1,593.3 billion zlotys of "GDP distributed." If the import surplus of 110.1 billion zlotys is considered as disinvestment, then the 615.1 billion zlotys shown above is reduced to 505 billion zlotys. If we reduce the GDP total by the import surplus (1,593.3—110.1=1,483.2), the correspondingly reduced gross investment (505) will amount to 34 percent. Each of the percentages of gross investment has to be interpreted with regard to its base.

Corresponding 1974 figures for Hungary may be obtained directly from the official Hungarian statistical yearbook, *Statistikai Évkönyv*, 1974, p. 79, where the national income in current prices is shown in the GDP concept. The total final use of GDP in the domestic economy is shown at 478,600 million forints, without reduction by an import surplus of 21,900 million forints. Total gross capital formation in domestic use was 166,700 million forints, or 34.8 percent of total final domestic uses. Taking into account the import surplus as a reduction of both the total domestic uses and the gross investment, the resulting percentage for gross investment becomes 31.7. A breakdown

<sup>9</sup> Eugenia Krzeczowska, "Dochód narodowy Polski w dolarach" (Polish National Income in Dollars), *Wiadomości Statystyczne*, 1976, No. 10, p. 2.

<sup>10</sup> *RS 1976*, pp. 66, 71-72.

of GDP by final uses for 1975 was not published in the 1975 issue of the Hungarian statistical yearbook.

We have not attempted to estimate the share of gross investment in GDP for the other East European countries, but from a glance at Table 5, and the relationship between net investment shares in current prices in the NMP national income distributed, one might guess that gross investment in 1975 in current prices in these other countries would account for GDP shares in the range indicated by Poland and Hungary. Table 5 does not provide 1975 current price allocations for East Germany, and a guess would not be warranted here.

Note: See appendix, notes to tables 4, 5, 14, 15, 16, etc.

Table 5 shows the allocation of "distributed" NMP national income in Eastern Europe for selected years, 1965-1975. As in the instance of Table 4 for the composition of national income produced, Table 5 shows the percentage composition in a number of different price bases as indicated by the footnotes to the table. It is immediately evident that the compositions by end uses in a single year will differ sometimes substantially, depending on the basis of valuation. For example, percentage distributions for Czechoslovakia are shown in current prices (footnote 3) and in constant 1967 prices (footnote 4) for 1966, 1970 and 1975. For 1966, net investment in current prices was 16.5 percent, and in 1967 prices, 20.6 percent; total consumption (shown by its components of personal and collective consumption) accounts for the balance, i.e., 83.5 and 79.4 percent in the respective prices. An impression of the changing structure over time is shown by the entries based on constant January 1, 1967 prices (footnote 4): net investment (accumulation) increases in percentages of NMP national income distributed as follows: 1966—20.6, 1970—23.3, and 1975—26.0; personal consumption declines correspondingly—60.3, 57.9, and 54.5; collective consumption accounting for the residual in the 100 percent was 19.1 in 1966, 18.8 in 1970, and 19.5 in 1975. The percentage distribution in current prices in 1975 was as follows: net investment—28.9, personal consumption—52.3, and collective consumption—18.8. The overall impression in the instance of Czechoslovakia is that net investment is increasing its share in both constant and current prices, while personal consumption is correspondingly declining, collective consumption rising, and total consumption falling.

We leave it to the reader to trace the detailed trends in shares shown in Table 5 for the other countries; we shall consider here only major overall trends. In Bulgaria the tabulated data suggest a somewhat increasing share being allocated to net investment (accumulation) with an offsetting decline in personal consumption. In East Germany, in 1967 prices, the investment share rose from 1965 to 1970 (from 19.9 to 24.0 percent) and then declined by 1975 (to 21.9 percent); consumption reflects offsetting changes. Hungary in constant prices shows fluctuations in the net investment share from 20.2 percent in 1965 to 24.8 percent in 1975; total consumption, as the remaining component in the total shows compensating changes, but collective consumption gains at the expense of personal consumption. In 1971 constant prices Poland experienced a growth in the share of investment from 21.8 in 1965 to 31.7 in 1975; personal consumption provided the major compensating decline (from 61.4 to 52.5). Romanian statistics on final uses appear to be deliberately blurred by being shown as averages over five-year intervals. The general impression conveyed by the table is a sustained substantial increase in the investment share from 24.3 percent in 1961-1965, to 34.1 percent in 1971-1975, with total consumption falling to accommodate this increase.

Table 5 shows allocations to final uses in current prices for selected years. Particular interest is attached to the 1975 current-priced shares as compared to their constant-priced corresponding shares. For the three countries where 1975 permits such comparisons, the percentage shares in current versus constant prices for personal consumption were, respectively, as follows: Czechoslovakia: 52.3 vs. 54.5; Hungary (total consumption): 71.1 vs. 75.2; and Poland: 54.8 vs. 52.5.

### Structure of Employment

A basic insight into the changing structure of economic activity is given by the distribution of employment among sectors of production. This is shown in Table 6 for 1960 and 1974 by major sectors for the CEMA countries of Europe and for other countries of Europe and the United States.<sup>11</sup>

<sup>1</sup> These figures refer to 1965, but the remaining entries in this row appear to be the percentage distribution of an unstated 1974 total.

<sup>2</sup> 1959, but remaining figures seem to refer to 1960.

<sup>3</sup> 1970, but remaining figures seem to refer to 1974.

<sup>4</sup> Includes construction.

<sup>5</sup> Excluding Northern Ireland.

<sup>6</sup> 1971.

Source: Poland, "Rocznik Statystyczny, 1976."

These data may not be fully comparable as to coverage, but the orders of magnitude are probably close enough for our rough purpose.

<sup>11</sup> Poland, Główny urząd statystyczny, *Rocznik statystyczny, 1976*, p. 54. These summary data from the Polish statistical yearbook were spot checked against the OECD, "Labour Force Statistics, 1963-1974," and found to be fairly consistent. Variations for the spot-checked items were around one percentage point. The Polish source provided a convenient summary and breakdown. The OECD source should provide more detailed definition of categories for Western Europe.

Some general conclusions drawn from this table are: (1) The economically active population in 1974 in the East European countries and the USSR comprises roughly one-half of the total population. In Western Europe and the United States the range is between 35 and 46 percent. The United States and West Germany show 44 percent; Italy is lowest at 35 percent; and Great Britain (1971) highest at 46 percent.<sup>12</sup> (2) As a percentage of the total economically active population, non-material services in Eastern Europe and the USSR have risen from a range of 9 to 15 percent in 1960 to a range of 15 to 22 percent in 1974. For the non-CEMA countries, the corresponding range for 1974 was 18 to 34 percent. (3) The percentage shares for the East European countries for industry have risen markedly from 1960 to 1974 for Bulgaria, Romania, Poland and Hungary; very slight increases appeared in Czechoslovakia and East Germany. For the region as a whole the 1974 range for the share of industry in the total economically active population was between 29 and 42 percent, with East Germany (42 percent) and Czechoslovakia (38 percent) at the top, and Romania and Poland at the bottom (30 percent). The 1974 corresponding range for industry in Western Europe was from 28.5 percent (France) to 41.3 percent (West Germany); for the United States the share was 26 percent. Thus in terms of industry's share in total employment, Eastern Europe is quite similar to Western Europe. (4) Agriculture's share in Eastern Europe fell sharply in all countries between 1960 and 1974. In 1960 the range was from a high of 66 percent in Romania to a low of 17 percent in East Germany. By 1974 this range had diminished to the high of 40 percent in Romania and the low of 11.4 in East Germany. In Western Europe agriculture's share also declined sharply. In 1974 the range was from 23 percent (Spain) to around 2.5 percent (Great Britain); for the United States the percentage was 4.0. The comparison suggests that agriculture still affords a labor reserve for transfer to non-agricultural sectors in Eastern Europe. Such transfer will depend on improved productivity in agriculture and the provision of employment opportunities and housing in the non-agricultural sectors.

Table 7 provides for countries of Eastern Europe the percentage composition of employment and indexes of growth of employment by sectors of production, 1965, 1970 and 1975. So far as the sectoral composition of employment is concerned, the data for 1975 are slightly different from those for 1974 shown in Table 6. The share for industry in the total employment showed only slight increases over the 1965-1975 period for Czechoslovakia, East Germany, Hungary and Poland, very substantial increases occurred in Bulgaria, and particularly in Romania (from 19 to 30 percent). In 1975 the range for the industrial shares for the six countries was from 30 percent (Romania) to 42 percent (East Germany), a remarkable reduction from the range in 1965 from 19 percent (in Romania) to 41 percent in East Germany. For agriculture and forestry the evolution of ranges was from 1965: 58 percent in Romania to 16 percent in East Germany, to 1975: 39 percent in Romania to 11 percent in East Germany.

<sup>12</sup> The 1974 figure for Great Britain indicated by the OECD source cited above was around 44 percent.

Other.....	9.8	11.2	12.5	100	118.9	135.4
Total.....	100.0	100.0	100.0	100	102.4	104.9

Note: See appendix, notes to table 7.

The indexes in Table 7 show the growth of employment by total and by sector, 1965, 1970 and 1975. Total employment increased most in Poland (26 percent) and least in Romania (5 percent) and in East Germany (4 percent). Employment in all sectors grew faster than total employment, except for agriculture and forestry, where it dropped by about 30 percent in Bulgaria, East Germany, and Romania, by about 18 percent in Czechoslovakia and Hungary, and by only 2 percent in Poland, and except for trade, which fell only in East Germany (by 4 percent). The faster growing sectors varied

among countries, but trade, construction, transportation and industry more or less in that order were the leaders. A significant exception here was industry in Romania (an increase of 68 percent, the highest sectoral growth).

Because industry is the largest sector in all countries, the changing composition of employment by branches of industry, 1960-1975, shown in Table 8 may be of interest. In all the countries the machinery branch, comprising metals, general machinery, precision machinery, transport means, and electric-electronic equipment, was from the outset the largest branch and continued to grow over the period. In percentages of total industrial employment, 1960 and 1975 respectively, this branch accounted for 36.4 and 42.5 in East Germany, 34.6 and 37.7 in Czechoslovakia, 27.9 and 31.6 in Hungary, 24.9 and 32.5 in Poland, 24.0 and 35.4 in Romania, and 16.7 and 25.4 (1974) in Bulgaria. Thus, by this indicator, the spread among countries has diminished. Some detail by sub-branches within machinery is shown for some of the countries; in Hungary and Poland (and probably in the other countries as well), the electric-electronic sub-branch has shown very rapid growth. In all of the countries textiles' share was important at the beginning of the period, but this share declined steadily up to 1975. The chemicals branch shows consistent growth over this period throughout the area.

<sup>1</sup> Total industry.

<sup>2</sup> 1960, 1965, and 1970: Ferrous and nonferrous industries; 1974: Ferrous industry only. The data are accordingly not comparable with previous years. One might note the sharp increase in 1974 in the share of "other industry"; this suggests a transfer from metallurgy to the "other" category, which includes an unspecified residual that we placed there.

<sup>3</sup> Not elsewhere specified.

Sources: See notes to tables 7, 8, 22, 23, and employment data in table 24, in the appendix hereto.

## Structure of Fixed Capital

Priorities in fixed capital formation are reflected in Table 9 in terms of shares in total fixed capital and indexes showing growth of fixed capital. In all six countries the share of industry is the largest in the national totals, and this share has increased over the 1965-1975 period. Transport and communications ranks second in this respect in all countries except Poland, where agriculture and forestry come second, and Romania, where transport and communications in 1965 ranked third but by 1975 had risen to second place. Agriculture, with the exceptions noted above, ranked third. The range for the share of industry in 1975 in percentages of the total was from a high of 42 percent in Romania to a low of 27 in Hungary. (These shares of course do not indicate the comparative levels of capital per worker; some of the lower ranking countries, e.g., East Germany and Czechoslovakia should stand above Romania on this count.)

TABLE 9.—OFFICIAL DATA ON THE STRUCTURE AND GROWTH OF FIXED CAPITAL, BY MAJOR SECTOR, 1965, 1970, AND 1975

<sup>1</sup> At full initial cost; cumulative value of assets added at current prices of the time of acquisition.<sup>2</sup> 1974. Detailed data for 1975 are not yet available.<sup>3</sup> At undepreciated purchase value, in comparable 1967 prices.<sup>4</sup> At undepreciated book value, in comparable 1966 prices.<sup>5</sup> At undepreciated value, in comparable prices of 1968.<sup>6</sup> Beginning of year data (Jan. 1, 1975).<sup>7</sup> Includes personal services.<sup>8</sup> At undepreciated value in prices of 1971.<sup>9</sup> Romanian data for 1970 reflect an expansion of the coverage of fixed capital data, concurrent with the expansion of the official concept of material product. Figures to the left are comparable to 1965 data in the old coverage; figures to the right are comparable to the 1975 data in the new coverage. Value figures to reconcile the 2 concepts are not available, and linked indexes for all sectors and groupings have not been published.<sup>10</sup> Year end data, at full purchase value; 1965 data reflect list prices of the time of acquisition; 1970 and 1975 data reflect prices of 1963.<sup>11</sup> Figures shown here are those given in yearbooks published since 1972; they reflect the redefinition, as of 1970, of all such services as "productive." Earlier data, however, yield larger shares for productive and nonproductive transportation and communications taken together; 16.6 percent in 1965, and 15.9 percent in 1970.<sup>12</sup> Includes forestry (0.1 in 1965 and 0.2 in 1970) as implied by comparison with figures on agriculture including forestry published earlier.<sup>13</sup> Includes communal and miscellaneous nongovernmental services.

Note: See appendix, notes to table 9.

The indexes show fixed capital growing most rapidly in the 1965-1975 period in construction in all countries; transport and communications ranks second in all countries except Romania and East Germany (where industry took precedence), and Czechoslovakia (where trade came second). Industry ranks third in growth except in Czechoslovakia where it yields precedence to agriculture. The miscellaneous "other material production" is not considered in this ranking. Fixed capital in the economy as a whole for 1965-1975 would appear to have grown fastest in Romania (2.4 times) and Bulgaria (2-fold), but fixed capital statistics considered as "real" measures are of dubious quality in these countries. Agriculture showed below average growth in fixed capital in all countries except Czechoslovakia, East Germany and Hungary.

*Dollar Estimates of GNP*

The total and per capita 1975 dollar values of GNP shown in Table 10 provide a rough orientation of the relative standings of the indicated countries. The figures for the six countries of Eastern Europe were calculated as in version B of my article for the previous JEC Compendium,<sup>13</sup> but account was taken of the revision of our GNP indexes, 1965-1975. The data for non-CEMA countries were converted from national currency values into dollars by the OECD 1975 average trade conversion factors. Because the methodologies underlying the estimates are not uniform and the conversion rates subject to improvement, we should allow for some deviation from results that would follow from a uniform methodology for conversions of final use GNP categories by exchange rates reflecting appropriate purchasing power parities of the various national currencies for all the countries that are compared.

According to Table 10, among the six East European countries the rankings in 1975 in current United States dollars per capita, rounded to the nearest 100, were as follows (Table 10): Czechoslovakia and East Germany at the top at 3,700, Hungary and Poland next at 2,400, and Romania and Bulgaria last at 2,200. East German and Czechoslovak GNP per capita in dollars was about 53 percent of that of West Germany and about 51 percent of the United States level. All the other countries of Eastern Europe would be near the level of Greece, and below Italy and Spain. In terms of the total GNP in 1975 in current US dollars, the six countries of Eastern Europe had a smaller total (289.4 billion) than France alone (337.9), and they would account for about one-fifth of the United States total and one-third of the USSR total.

TABLE 10.—TOTAL AND PER CAPITA DOLLAR VALUES OF GNP, 1975

[In 1975 U.S. dollars]

	Total (Billions)	Per capita
1. Bulgaria.....	\$19.0	\$2,180

15. Japan.....	491.0	4,425
16. United States.....	1,516.3	7,099

Sources: Items 1-6. See appendix, notes to table 10. Non-CEMA countries: "Statistical Abstract of the United States 1976", p. 877. U.S.S.R.: U.S. Congress, Joint Economic Committee, "Soviet Economy in a New Perspective", p. x.

There are published some estimates of the GNP of Poland and Hungary that may be compared to our figures in Table 10. First, we

<sup>13</sup> Thad P. Alton, "Economic Growth and Resource Allocation in Eastern Europe" in U.S. Congress, Joint Committee Print, "Reorientation and Commercial Relations of the Economies of Eastern Europe," August, 1974, p. 268.

take the figures for Poland published by Dr. Eugenia Krzeczowska of the Institute for Statistical Economic Research in the Polish Main Statistical Office (*Główny urząd statystyczny*).<sup>14</sup> Krzeczowska expanded the Polish official figure for gross national income produced (the net material product plus depreciation on fixed capital in the material product sector) to the United Nations SNA definition of gross domestic product. She did this by adding the net value added by non-material services plus their depreciation of fixed assets and making adjustments for imputations for rent and profit in the housing sector, and by subtracting the value of non-material services bought by the material sectors and appearing in their net material product. (In calculating the net material product national income, only material costs are subtracted from gross output; the non-material costs remain in the net material product of the buying material product sector.) The result was a value for 1974 GDP in zlotys.

In translating the zloty value to US dollars, Krzeczowska proceeded by reference to bilateral France-Poland comparisons of personal consumption from personal incomes in purchasing power indexes of their currencies in 1972 and 1973, and then linked the result to the US dollar. The consumption category was broken down into foods, beverages, clothing, shoes, household equipment, fuel, electricity, water, gas, personal hygienic articles and cultural services. The findings were advanced to 1974 by indexes. For the remaining end-use categories (consumption financed by social funds, investment construction, and machinery and equipment for investment), she proceeded by use of the bilateral United States-Hungary comparison carried out by the United Nations International Comparisons Project (ICP),<sup>15</sup> and bilateral Hungary-Poland comparisons prepared by research and analysis units of the respective national statistical offices. Krzeczowska found that the average relation of the zloty to the dollar in 1974 was \$1.00=20.6 zlotys. She translated the result into Polish GDP per capita in 1974 equal to 2,167 current dollars, and she further roughly extrapolated this to obtain the estimated 1975 per capita Polish GDP at 2,325 US dollars. Our calculation in Table 10 shows 2,440 dollars, about 5 percent above Krzeczowska's estimate.

We may also compare our Table 10 figure for Hungary with the findings of the United Nations ICP Project cited above.<sup>16</sup> The ICP figures we use refer to the 1970 Hungary-United States binary comparison of purchasing power of currencies. The ICP figure for US per capita GDP in 1970 is \$4,798.59. The Hungarian per capita counterpart in Hungarian weights is \$1,554.74. If we advance this figure to 1975 by our index of Hungarian GNP per capita (see Table 12) and apply the US implicit GNP deflator, the Hungarian per capita figure in 1975 dollars becomes \$2,526. Our Table 10 figure is \$2,390. The ICP study also provides figures at US weights and at the Fisher ideal or geometric average weights. Updated to 1975 and expressed in 1975 dollars these figures become 3,703 (US weights) and 3,056 (ideal weights).<sup>17</sup>

<sup>14</sup> Eugenia Krzeczowska, "Dochód narodowy Polski w dolarach" (Polish National Income in Dollars), *Wiadomości statystyczne*, No. 10, pp. 1-3.

<sup>15</sup> See Irving B. Kravis, Zoltan Kenesey, Allen Heston and Robert Summers, "A System of International Comparisons of Gross Product and Purchasing Power." The Johns Hopkins University Press, Baltimore, 1975.

<sup>16</sup> Kravis, et al., *op. cit.*, p. 173.

<sup>17</sup> The US GNP deflator used here is that given in "Survey of Current Business," January 1976, pp. 84-85; *ibid.*, June 1976, p. S-2; and revised figures, 1973-1975, in *ibid.*, February 1977, p. S-2.

International binary comparisons of national products and purchasing powers of currencies face the usual ambiguities under the heading of index number problems. In practical application there are problems of defining products with adequate specificity so as to facilitate the matching of prices, problems of choosing suitable baskets of products for lower level prices indexes, and further problems of determining suitable weights at higher levels of aggregation. In a single country for purposes of intertemporal comparison, the task is very difficult; the analogous international comparisons are even more formidable. All who work to resolve these problems make a valuable contribution to our understanding of comparative economic development, and their work should be seriously studied. The ICP study represents such work.

Binary comparisons have been made also between CEMA countries and between particular CEMA countries and countries of Western Europe. There is always an interest in the extension of a given binary comparison through linkage to other binary comparisons. Thus a comparison of a given CEMA country with a non-CEMA country could be extended to all CEMA countries that already have been compared and to non-CEMA countries that likewise have been compared. What results would follow from a number of such extensions are at this time speculative, and such results might be reassuring or they might strain credulity. In any event, the outcomes should not inhibit further research to place international comparisons on sounder bases.

One possible difficulty here may spring from use of antiquated price lists still in effect in some countries for their internal price index calculations even though a number of products corresponding to such prices no longer are being offered for sale, and those prices have ceased to reflect adequate relative comparability to products actually being offered. Domestically this might conceal the actual extent of the increased cost of living or inflation in other expenditure categories. In Eastern Europe the pressures upon enterprise managements to make a favorable showing are believed to have promoted spurious innovations or design changes to qualify an essentially old product as a "new" one, with a higher price. Of course such manipulation would not be unknown in Western countries, but probably competition would tend to suppress it. How to cope with such a problem is something for economists working on international comparisons to consider.

### III. INDEXES AND RATES OF GROWTH OF NATIONAL PRODUCT

Indexes of real GNP and the NMP national income are shown in Tables 11-16, and the corresponding annual growth rates for the 1965-1976 period are given in Tables 17-21. Both sets of tables present essentially the same information, but more detail is evident in the annual index numbers. Some comparable data on rates of growth are also presented for non-CEMA countries. Methodological comments and source references for the tables are provided in the appendix to this paper.

#### *Indexes of National Product*

Our GNP indexes are calculated as aggregations of indexes of sectors of origin of product in constant prices. Weights for the aggregation of sectors into the overall GNP index are factor cost approxima-

tions of the sectoral shares in a selected base year, generally in the late 1960s. These weights comprise returns to labor, a net return to the current value of fixed and working capital, a return to agricultural land, and depreciation of fixed capital.<sup>18</sup>

The NMP national income measures represent sectoral gross output less material cost, including depreciation. Non-material services are excluded from the NMP measure, although the sales of such services to the material sectors appear as part of the net material product of the purchasing sector. Such purchases, being non-material cost, are not subtracted from gross output in arriving at net material product. The NMP indexes were calculated for successive subperiods in sets of new constant, or comparable, prices for each such subperiod, and the subperiod indexes were chain linked into the index for the entire period. Because the GNP and the NMP national income concepts differ in coverage, methodology and bases of valuation, one should not expect necessarily close agreement in the overall indexes or in corresponding sectoral indexes.

The official NMP measures were taken directly from the national statistical publications. No changes were made to compensate for reclassification of economic activities; such changes in sectoral boundaries are often indicated in footnotes and introductory texts to the national income chapters of the national statistical yearbooks. However, retrospective changes in the published indexes are rarely made: thus there would follow inconsistent coverage in the published series. In the 1965-1975 period Bulgaria and Romania added passenger transportation and communications serving non-material sectors to the material product sphere; Czechoslovakia so far remains the only country among the six that has not made this change.

Not enough detailed information is provided on the official sectoral indexes to make a systematic comparison of their methodology and bases of valuation with ours. It is clear, however, that the official measures in actually realized market prices result in very substantial deformation of the structure of production from what it would be at approximations to factor cost. In the instance of Poland, the state statistical office recalculated the structure of national income (NMP) produced in three sets of approximations to factor cost and compared the results to the structure at the actual, realized market prices.<sup>19</sup> This exercise was emphatically described as only an illustration of the problem. We have indicated the results of the recalculations above.<sup>20</sup>

When prices were adjusted to correct for distortions from cost introduced by turnover tax, other taxes, positive and negative budget differences and subsidies in variant A, and when prices were adjusted in variant B to make them proportional to the cost of direct labor inputs by redistributing the financial accumulation manifested in profits and state levies, and finally, when the revaluation under variant B was augmented in variant C by providing a return to fixed capital, the consequences for the structure of the NMP national income produced were very striking. For the year 1967 the share of industry in total national income fell from 51 percent in realized prices to 41 in variant C; the share of agriculture rose from 19 to 27

<sup>18</sup> See our "Occasional Papers," No. 48, "Statistics on East European Economic Structure and Growth," and No. 50, "Economic Growth in Eastern Europe, 1965-1975," for detailed descriptions of our weights, methodology, and sources. Some revisions have been made for the present paper.

<sup>19</sup> See Poland, Główny urząd statystyczny, *Rocznik dochodu narodowego*, 1971 (Yearbook of National Income, 1971), p. 214 ff.

<sup>20</sup> See p. 211.

percent; transport and communications rose from 8 to 13 percent; and trade fell from 9 to 6 percent. This brief recapitulation of part of what we discussed above is mentioned here to raise the question of what consequences would follow for the rates of growth of the NMP national income and which of its sectors and subsectors would be affected.

One may conclude that the planners in Eastern Europe may have their rationale for the system of market prices, designed in the initial instance to provide convenient revenue flows to the state to implement their plans for investment, collective consumption, and redistribution of income, among other aims, but that such prices mask the economic realities as regards factor costs. Some price reforms have corrected a part of the distortion in earlier prices in some countries at various times, but these reforms were not sufficiently comprehensive, and in some cases have been eroded, so that the official indexes still must be viewed with circumspection.

A further comment on official "constant" prices for a specified time segment seems warranted here. It concerns the pricing of new products. It is believed that new industrial products are introduced at initially high "constant" prices with the intention later to replace these "constant" prices by new, lower constant prices when the scale of production increases, but that such reductions are not made as expected. Moreover, some spurious innovations masking an essentially unchanged product are used by enterprises to set higher constant prices.

Our indexes are not alleged to be beyond fault, but we have tried to maintain a generally consistent approach in the measures for various countries as regards methodology and sectoral weights, among other considerations. Our industrial production indexes reflect civilian production with the exception primarily of Czechoslovakia, where we have made a substantial adjustment to account for production of military hardware. Some representation for military production also was incorporated in the Polish industrial production index. If the output of military hardware does not match the trend in civilian production, our measures would be deficient. We may also be conservative as regards inclusion of new products, but we are limited in our calculations by the sample of products published by the statistical offices of the East European countries. Whether the published series are selective in the sense of showing disproportionately the faster growing series is a matter for speculation, but perhaps on this count there may be some upward bias. In any event, an independent approach to the estimation of trends in production would seem justified.

Tables 11 and 12 present our indexes of overall and per capita real GNP. Both tables show roughly similar trends, but Table 12 shows slower growth because it reflects the population growth in the various countries. The rank by extent of growth is the same in both tables. In the 1965-1976 period Romania was highest in growth of total GNP (87 percent), followed by Poland (77 percent), and Bulgaria (69 percent). The remaining three countries were clustered (at around 40 percent). The range of growth in Table 12 is narrower, from 66 percent (Romania) to 34 percent (Hungary) because the faster growth in total GNP shown in Table 11 was slowed down more when shown per capita in Table 12 in those countries whose

population grew relatively faster. East Germany, with an absolute decline in population, showed higher per capita GNP growth than total GNP growth. The population indexes are shown in Table 1.

Source: Tables 1 and 13. Calculations were done from unrounded indexes.

Table 13 shows the detailed array of our sectoral real GNP indexes and the weights used to combine them into overall GNP. The sectors of construction, trade, transport and communications, and industry are generally the faster growing ones, but their rank varies from country to country. Agriculture in all countries grows less rapidly than overall GNP. Because industry and agriculture are the more heavily weighted sectors, their influence upon the growth of overall GNP is decisive.

Table 14 presents the official NMP sectoral and national income produced indexes. The indexes shown for particular sectors over the 1965-1976 period in particular countries are various, but the faster growing sectors are, as in Table 13, construction, trade, industry and transport and communications, in various order depending on the country. Agriculture shows below average growth in all countries. The impact of weather on agricultural performance appears in the fluctuations of the sectoral index.

The official real NMP national income produced indexes per capita are given in Table 15. They are lower than the corresponding total indexes because Table 15 reflects population growth directly. Only East Germany experienced an absolute decline of population, and accordingly its indexes of per capita growth in Table 15 reach higher levels than the corresponding indexes in Table 14.

1976.....	222.3	182.0	175.7	185.9	210.0	242.0

Note: Calculated from official NMP indexes in table 14 and population data in table 1; calculations were done from unrounded figures.

We have not maintained up-to-date indexes of final uses of GNP in Eastern Europe. The official indexes, 1965–1975, of the NMP national income distributed are shown in Table 16. The immediate conclusion that this table conveys for all countries is that net investment (accumulation) grew faster than the average shown by the total NMP national income distributed, and total consumption, comprising personal consumption and collective or social consumption, grew slower than the average. Within the total consumption, the collective consumption (shown as "other" in the table) index grew faster than personal consumption. In East Germany, a singular instance, the collective consumption index ("other") grew faster than net investment.

<sup>1</sup> Estimates from incomplete preliminary data.

Note: These data are not entirely comparable among countries. See the appendix, notes to tables 4, 5, 14, 15, 16, 19, 20, 21, and 24.

Personal consumption is not uniformly defined among the countries of Eastern Europe; in some instances it refers to material products and material services bought by the population from their personal incomes; in other instances it also includes some state financed consumption by the population. In all categories of national income distributed the reference is to material product. The total available for distribution differs from the total NMP national income produced by the import (or export) surplus and by losses of national income produced. Accordingly, the indexes of total NMP national income distributed may differ from those of the NMP national income produced.

### *Rates of Growth of National Product*

The annual indexes of GNP and NMP national income provide detailed observations on economic trends, but they do not contribute to the more facile interpretations made possible by annual average rates of growth over selected periods of years. We show below such rates calculated by least squares fittings of the exponential growth equation,  $I_n = I_0(1+r)^n$ , to the annual observations. Here,  $r$  is the compound rate of growth,  $n$  the number of years, and the  $I$  refers to the index values. Tables 17 to 21 make explicit the average rates of growth implicitly shown by the annual indexes in earlier tables.

In Table 17 are shown the average annual rates of growth of GNP (or GDP) for six countries of Eastern Europe and for selected other countries. The rates for Eastern Europe are based on our GNP estimates; those for other countries are GDP (gross domestic product) rates provided in the most recent United Nations *Yearbook of National Account Statistics*. Economic growth in 1974-1975 was depressed in the United States, Japan and Western Europe as a consequence of the sharply increased prices of imported petroleum and other factors.

Sources: East European countries: Calculated by least squares fit of  $I_n = I_0(1+r)^n$  to indexes in table 13. Other countries: United Nations, "Yearbook of National Account Statistics," 1975, table 4A. (Also by least squares fit.) 1975: United States, "Statistical Abstract," 1976, p. 877 (GNP rates).

Comparison among countries and between the six CEMA countries on one hand and the nine non-CEMA countries on the other at best can be superficial. Ideally one should compare performance of countries at about equal levels of economic development and under circumstances where some extraordinary exogenous factors do not disrupt the course of development. However, if we disregard these strictures and simply consider the performance of the countries in the same time spans, a general impression of comparative rates of growth may be gained. We have noted earlier in our discussion of the sectoral composition of employment and national product that at least from that point of view the countries of Eastern Europe are becoming more like the Western countries, although considerable disparities still exist among the countries in each group and between the two groups.

In the 1965-1970 period the overall impression is that the non-CEMA countries, with the notable exception of the United Kingdom and the United States, grew much more rapidly than the countries of Eastern Europe. The unweighted average rate for Eastern Europe was 3.2 percent; for the group of other countries the corresponding rate was 5.1 percent, despite the roughly 2 percent rate shown by the United Kingdom and the United States. The ready-made rates for the other countries are given in our source for 1970-1974, a shorter period than the 1970-1975 span for Eastern Europe, for which we computed the average rates. Thus comparison of the average performance of the two groups is not so immediately gained from the table. However, if we take into account the rates for 1975 shown in the last column of the table for the "other countries," it seems clear that Eastern Europe on the whole grew faster, around 4.1 percent on the average. Over the longer span, 1965-1975 for Eastern Europe and shorter, 1965-1974 period for the other countries, the latter group shows a higher average rate. Inclusion of 1975 in a least squares fit for the 1965-1975 period for the latter group should lower somewhat its average rate since 1975 witnessed largely negative or sharply decreased growth rates for this group.

Averages, such as the ones noted above, hide the more interesting individual country trends. Within Eastern Europe the less developed countries, Romania, Bulgaria and Poland, showed higher rates of growth than the remaining countries. In the non-CEMA group, Japan was the best performer. The less developed countries, Greece and Spain, grew faster than the other countries in this group. The United States and the United Kingdom ranked lowest in rate of growth.

The overall growth rates shown in Table 17 are shown in sectoral detail in Table 18 for the East European countries. These rates confirm the general impression gained from our examination of the corresponding sectoral indexes shown in Table 13. Trade, construction, and transport and communications stand out in most countries as the more rapidly growing sectors over subperiods of 1965-1975 and over the period as a whole. Industry, the largest sector, shows considerably above average rates of growth except in Hungary in the 1970-1975 period. In Romania industry grew faster than any other sector. Agriculture and forestry grew more slowly than overall GNP in all countries except East Germany and Hungary in the 1970-1975 period. Housing also was a below average growth sector.

<sup>1</sup> By least squares fit of  $I_t = I_0 (1+r)^t$ . Calculated from table 13.

Overall NMP national income per capita growth rates for the East European countries are shown in Table 19 for the 1965-1976 period and for subperiods. The least developed country, Romania, shows the highest growth rates, averaging 8.1 percent over the 1965-1975 period. In the same period the other countries in descending order of growth rate per capita were Bulgaria (7.3), Poland (6.9), Hungary (6.0), Czechoslovakia (5.7), and East Germany (5.4). For the more recent period of 1970-1975, the rank order is the same as for 1965-1975, except that Poland precedes Bulgaria. The less developed countries grew faster than the more developed ones in terms of NMP national income per capita; this conclusion follows also from our earlier consideration of GNP growth rates.

TABLE 19.—AVERAGE ANNUAL RATES OF GROWTH OF NET MATERIAL PRODUCT PRODUCED PER CAPITA, 1965-76<sup>1</sup>  
[At constant prices; percent]

Romania.....	6.2	10.2	8.1	9.4

<sup>1</sup> By least squares fit of  $I_n = I_0(1+r)^n$ , calculated from table 15.

Table 20 shows average annual growth rates of total and sectoral NMP national income produced, 1965-1976. The growth rates for the total correspond closely to those shown for the per capita total rates in Table 19, but are lower in Table 19 because of the increasing populations in all countries except East Germany, for which the conclusion must be reversed. The rank of sectors by rates of growth of net material product shows considerable similarity among the countries. Agriculture is the slowest growing sector. The anomalous negative 21 percent rate for Romanian trade for 1965-1970 is some kind of statistical aberration probably springing from the definition of NMP in trade to include price equalization outcomes in foreign and/or domestic trade, rather than an approximation to services actually rendered by trade. Nevertheless, the strange behavior of the trade NMP index seems to have been incorporated into the overall NMP national income in constant prices. What the procedure in this respect is for the post-1970 years is not explained in the few sources we have seen, but the discontinuation of the index for "other" suggests that some masking may occur here pending a revision of concepts and methodology. In all countries, trade, construction, and industry, more or less in descending order of growth rate, are the faster growing sectors (with the official Romanian trade NMP index a special case, as noted).

<sup>1</sup> By least squares fit of  $I_n = I_0(1+r)^n$ . Calculated from table 14.<sup>2</sup> Forestry is not included among the residual "other" sectors, but is included in total NMP.<sup>3</sup> Publication of an NMP series for the trade sector was discontinued in Romanian statistical sources after 1970. An evidently revised series for the trade sector of Romania appears in CEMA yearbooks, without, however, any methodological clarifications or any concomitant revision of the measures for the growth of NMP as a whole. The CEMA series, thus, does not seem to be consistent with the main body of Romanian NMP statistics.

Table 21 shows average annual growth rates for the NMP national income domestically distributed, 1965-1975, by totals of indicated categories and also per capita for the overall national income distributed. The domestically distributed NMP national income differs from the NMP national income produced by the import (or export) surplus and the losses of national income produced. (An import surplus allows more to be distributed than was produced; losses operate in the opposite sense.) The interested reader can trace for himself the variations in the rates for the total national income distributed overall and per capita shown in Table 21 and the corresponding rates for national income produced (Tables 19 and 20). Factors accounting for differences most probably are to be found in variations in agricultural output, state policy with respect to augmenting consumption by means of foreign loans, and eventual repayment of such borrowings by export surpluses.

<sup>1</sup> By least squares fit of  $I_n = I_0(1+r)^n$ . See appendix, notes to tables 4, 5, 14, 15, 16, 19, 20, 21, and 24.

Note: Data for Romania are not available.

It is clear from Table 21 that over the 1965-1975 period net capital formation took priority over personal consumption in all the countries. The exception to this regularity is found only in the 1970-1975 subperiod and only in East Germany and Hungary, where consumption showed higher average annual rates of growth. Within the consumption total, personal consumption never exceeded and rarely equalled the rate of growth of total consumption, implying that collective consumption grew faster than personal consumption. Romania does not publish annual indexes of end uses of national income and therefore could not be included in Table 21.

#### IV. RATES OF GROWTH OF FACTOR INPUTS AND LABOR AND CAPITAL PRODUCTIVITIES

##### *Labor Inputs and Labor Productivity With Respect to GNP*

Table 22 shows average annual rates of growth of employment in the national economies overall and by GNP sectors, and Table 23 presents the corresponding rates of growth of labor productivity. Poland ranks first in the annual rates of increase of total employment in 1965-1975 and in the 1965-1970 and 1970-1975 subperiods, with average rates around 2.3 to 2.5 percent. For the long span, 1965-1975, Czechoslovakia ranks second (1.4 percent), Bulgaria third (1.1 percent), Hungary fourth (1.0 percent), and East Germany and Romania last (0.4 percent). For the most recent subperiod, the ranking is practically the same as that just noted for 1965-1975, except Bulgaria becomes second, swapping rank with Czechoslovakia.

<sup>1</sup> By least squares fit of  $I_n = I_0 (1+r)^n$ . Calculated from annual average employment and the GNP indexes in table 13.

Note: Figures reflect GNP concept definitions. See the appendix, notes to tables 7, 8, 22, 23, etc.

The expected and notable decline in employment in agriculture and forestry is evident for each of the countries. The annual rates of decline in this sector are highest in East Germany, Bulgaria, and Romania, followed by Czechoslovakia and Hungary. Poland shows insignificant negative rates of growth of agricultural employment over the entire period. In most of the countries, the trade sector shows the most rapid rates of growth; in second rank come construction and industry, with some change in order of ranking in the various countries.

Increases in employment and the associated average annual rates of increase of employment reflect the demographic structure of the population and the participation rates of the population in employment. Here, we shall consider briefly only the changes in participation rates for 1960, 1970, and 1974. Participation in the tabulation below is defined as the number of persons actually engaged in economic activity per 100 of the relevant total population, identified by T = total population, M = total male population, and F = total female population. For the sake of comparison, some Western countries are included in the tabulation. The data for the six East European countries are taken from their national statistical publications; those for the USSR and Western countries are taken from Table 6.

1 1959. \* 1961. # 1962. † 1975.

In Eastern Europe and the USSR, the participation rates in the total population (T) by 1974 had reached around 50 percent. There was an increase from 1960 to 1970 in five of the six East European countries (Bulgaria shows a slight decline), but from 1970 to 1974 the rates remained relatively unchanged. Some declines in the male participation rates were offset by gains in female participation, notably in Czechoslovakia, East Germany, Hungary, and to a lesser extent, Bulgaria. The highest participation rates are shown in Poland, and more detailed information in the Polish source shows that high rates in agriculture (Totals: 1960=58.1, 1970=62.7, and 1974=62.1, with almost equal rates for males and females) raise the average rates for the economy as a whole.

Participation rates in Western countries have declined from 1960 to 1974, and for the latter year fall in the range of 35.4 (Italy, 1975) to 46.3 (Great Britain), with the United States and West Germany about 44 and the remaining countries between 38 and 42. The comparison suggests that the Western countries apparently have more scope for increasing their participation rates than the countries of Eastern Europe. An explanation of the diverse rates of participation no doubt would entail examination of national customs, achieved levels of economic efficiency and output, the need to maintain or desire to raise the level of living of family units, the changing status of women to greater equality vis-a-vis men, and a host of other related socio-economic and cultural considerations that cannot be analyzed here.

Table 23 shows average annual rates of growth of labor productivity (GNP divided by employment). In the most recent interval, 1970-1975, for total GNP, the rankings in percentage rates of growth of labor productivity from highest to lowest were as follows: Romania (5.6), Poland (4.1), Hungary (3.2), Bulgaria (3.1), East Germany (3.0), and Czechoslovakia (2.2). This ranking represents some striking changes from the 1965-1970 period; Romania still ranks first (4.0), Bulgaria comes second (3.8), followed by East Germany (2.9),

Czechoslovakia (1.8), Hungary (1.5), and Poland (1.3). For most countries the more recent period shows higher rates for overall GNP. In industry, in the 1970-1975 period, labor productivity growth rates declined from 1965-1970 in four countries (Bulgaria, Czechoslovakia, East Germany, and Romania) and increased in two (Poland and Hungary). We leave it to the reader to study the various detailed changes by country, sector, and time periods. Agriculture experienced a poor year in 1976 in terms of labor productivity in four of the five countries shown in Table 23; Bulgaria evidently had a good year.

We do not show here the capital productivities (GNP divided by capital stock), in indexes or annual average growth rates, because of misgivings as to the quality of the fixed capital series for some of the countries and their compability with our GNP series. However, a general impression of capital productivity trends may be gained by examining the data in Table 9 on official indexes of fixed capital and Table 13 showing our overall real indexes of GNP and its production sectors. The general impression is that capital grew faster than the corresponding gross value added in production, but there were a few exceptions.

*Labor and Capital Productivities With Respect to NMP National Income*

Table 24 presents indexes based on official East European data on NMP national income produced, employment, and fixed capital for the overall national income and three major material product sectors. The indexes of labor productivity (net material product per unit of labor) are calculated by dividing the NMP originating index by the corresponding employment index; the indexes of capital productivity (net material product per unit of fixed capital) are constructed in the same manner. The capital-labor ratio index is the quotient of the fixed capital index over the employment index.

Source: See appendix, notes to tables 4, 5, 14, . . . and 24.

The indexes of labor productivity, capital productivity, and the capital per unit of labor ratio are of particular interest. Some reservations as to the correspondence of these indexes to some standard of acceptability based on consistency of the output measures over time in relation to corresponding consistency of the labor and capital measures should be made clear.

The labor series probably are the most consistent over time despite some changes in number of work days per week or per year and changes in hours worked per day, week or year. We have noted also that administrative changes sometimes shift non-productive labor from government into a material production sector, thus affecting con-

sistency in the labor input series. Nevertheless, so far as uniformity and consistency are concerned, the labor indexes probably are more satisfactory than the output and capital indexes. We have already noted the repercussions upon output indexes that one might expect as consequences of linking segments of the output indexes calculated at different prices. Our concern with regard to the capital series relates to the constancy of their valuation (Bulgaria and Romania are notable here). The procedures for establishing "constant" prices may in fact result in prices close to current, perhaps significantly inflated, prices: What the net result of such pricing may be when taken into account with the official output series, also probably inflated to some degree because of the pricing procedures for new products, is speculative. But it would appear less hazardous to use the official capital indexes in conjunction with the official NMP output indexes than in conjunction with our GNP indexes. In any event, the results shown in Table 24 may indicate some significant trends in economic activity.

With few exceptions, labor productivity over the 1965-1975 period has grown less rapidly than its corresponding output measure. The exceptions are agriculture in all six countries and total national income-labor productivity in East Germany. Over the 1965-1970 period, the observation that we made for 1965-1975 holds here as well, together with the same exceptions. By shifting the indexes shown in Table 24 to 1970=100, one may see that this observation holds also for 1970-1975, but with the changes that labor productivity in Bulgarian agriculture grew less rapidly than the NMP in that sector, and labor productivity growth exceeded the growth of NMP in East German construction.

A comparison of the increase in labor productivity in the two subperiods, 1965-1970, and 1970-1975, presents a mixed picture. This will be evident upon comparing the 1970 index (Table 24, 1965=100) with the 1975 index (1970=100, not shown in Table 24). In Bulgaria, the growth of labor productivity was slower in 1970-1975 than in the previous period for national income as a whole and for each of the three indicated sectors. The same observation holds for Czechoslovakia, except that industrial labor productivity rose insignificantly in the more recent period. In East Germany in the 1970-1975 period as compared to 1965-1970, labor productivity increased slightly in industry and substantially in construction, but fell in agriculture. Similarly Hungary registered improvement except for a small decline in construction. Poland showed improvement in all the indicated sectors. Finally, Romania showed increases under overall national income labor productivity and in agriculture, but presented declines in industry and construction. The general impression based on the summary measure of the labor productivity index with respect to the overall growth of national income is that in Bulgaria and Czechoslovakia the rate of growth of labor productivity has declined; in East Germany it has leveled off, and in Poland and Romania it has increased significantly.

In all countries for overall NMP national income and its component sectors, the capital productivity indexes have grown much more slowly than the corresponding output measures in the overall 1965-1975 period and in both of the subperiods. A comparison of trends in capital productivity in the 1965-1970 and 1970-1975 subperiods may be made

from the data shown in Table 24 by juxtaposing the index for 1970 based on 1965=100 with an index for 1975 based on 1970=100 (not shown in Table 24). A mixed impression follows from such a comparison. In general, capital productivity in both subperiods in the various countries showed trends over the five-year intervals falling within a range of a maximum 12.4 percent increase (with respect to Czechoslovak overall national income in 1965-1970) to a maximum decline of 33.2 percent (in Bulgarian agriculture in 1965-1970). At the overall national income level, the capital productivity indexes in the 1965-1970 period (1965=100) and in the 1970-1975 period (1970=100), respectively, were as follows: Bulgaria—91.1 vs 109.0; Czechoslovakia—112.4 vs 99.8; East Germany—101.8 vs 97.4; Hungary—105.0 vs 97.8; Poland—100.4 vs 110.2; and Romania—86.8 vs 97.6. For the production sectors shown in Table 24 the declines outnumbered the increases by 12 to 6 in each of the subperiods. The capital productivity indexes for the industry sectors of the six countries in the two subperiods fell within a range of 9.1 percent maximum increase (Czechoslovakia in the 1965-1970 period) to a maximum decline of 2.4 percent (East Germany in 1970-1975). There is not much significance to be read into these figures; the labor productivity measures implicitly reflect the cooperation of capital in production.

We have refrained from calculating joint factor productivities in the present paper. The capital/labor ratio indexes (reflecting the amount of capital per unit of labor) show overall higher gains in 1970-1975 (five countries) than in 1965-1970 (one country). The interested reader may wish to trace the comparisons by subperiods for particular sectors of production. However, one may observe that this measure as well as the capital productivity measure may reflect variant behavior over time depending upon investment priorities, and regulations concerning length of productive life of machinery, other equipment, and structures. If the observed trend toward setting sharply higher depreciation rates signifies actual shorter production lives and accordingly stepped-up scrapping rates, the capital measures shown in Table 24 would have to be interpreted accordingly. In any event one would have to consider the impact of technology upon factor productivities and output.

Much of the fixed capital stock in East European countries has become obsolescent when judged by Western standards. In an effort to speed up the elimination of deadwood in the fixed capital park, the average levels of depreciation rates have been raised and increased emphasis is being placed upon modernization of machinery, equipment and production processes, and less stress is given to construction of new plants. In all of the countries there was a period of rapid growth by extensive methods, relying on transfers of less than fully employed workers in agriculture into non-agricultural sectors, especially industry, and on higher rates of participation of women in employment. Such reserves for growth are dwindling; future growth will be increasingly dependent upon growth of labor productivity. Recognition of this prospect lies behind the eagerness of Eastern Europe to import the latest technology embodied in new capital equipment and production processes of Western countries.

## V. PROSPECTS AND PROBLEMS

Some indications as to how the countries of Eastern Europe and the U.S.S.R. envision resource allocation and economic growth in the 1976-1980 period as compared to their plans and performance in the 1971-1975 period are presented in Table 25. With the sole exception of Bulgaria, all of the countries are planning for slower growth of national income produced than was realized in their recently completed five-year plans. The less developed countries have set the higher goals for national income growth in their current five-year plans (in percentages): Romania—11; Bulgaria—8.2 to 8.7; Poland—7.0 to 7.3; Hungary—5.4 to 5.7; East Germany—4.9 to 5.4; and Czechoslovakia—4.9 to 5.2.

<sup>8</sup> Real.

Source: United Nations, supplement to "World Economic Survey, 1975," (1976).

The goals set for total real consumption and real gross fixed investment may suggest the priorities for national income distribution, but

comparisons drawn from the table cannot be precise for two reasons: (1) the table does not show national income distributed, which differs from national income produced by the import or export surplus and losses of national income produced; and (2) the table entry "total real fixed investment, gross" differs from "accumulation" or "net investment", which is usually shown as a component of NMP national income.

Total real gross fixed investment is planned to grow faster than national income produced in Czechoslovakia, East Germany and Romania, and slower in the other countries. Real consumption goals are shown in Table 25 only for East Germany and Hungary, where their planned growth is less than the planned growth of national income produced. The Hungarian planned growth rates for both total real consumption and total real gross fixed investment are lower than the rate for national income produced.

Rates of growth of total retail sales in real terms are shown in Table 25 for Bulgaria, Czechoslovakia, Hungary and Romania. Insofar as this indicator may serve as a substitute for total real consumption, it suggests that the latter will grow less than the national income produced; however, retail sales may grow at the expense of farm consumption in kind, and such sales may grow also by substitution of ready made goods for work done by housewives in food preparation, sewing, etc. The difference in planned rates of growth between real gross fixed investment and real consumption (or real retail sales) is greatest in Romania (12.9 percent versus 7.0 to 7.7 percent).

A comparison of actual rates of growth of real gross fixed investment in 1971-1975 with plans for 1976-1980 show expectations of slightly faster growth for Bulgaria, somewhat faster growth for East Germany, essentially no change in rate for Romania, a significant decline for Czechoslovakia and Hungary, and a very sharp decline for Poland (from 18.3 percent annual rate in 1971-1975 to a planned rate of 6.5 to 7.0 in 1976-1980). Poland had been benefiting from foreign loans in the past five-year plan and evidently is planning to live more within her own means in the current five-year plan. This is clear also in the planned deceleration of (nominal) retail sales, from 12.5 percent realized in 1971-1975 to 7.3 to 7.7 percent planned for 1976-1980.

A review of the performance of the economies of Eastern Europe in the 1965-1970 and 1970-1975 periods (Tables 18 and 20), taken in conjunction with their plans for 1976-1980 (Table 15) shows a generally declining trend for overall GNP (1965-1970 vs 1970-1975) and for overall NMP national income produced. Bulgaria displays a small decline in the juxtaposition of average annual rates of growth for the two past periods in both the GNP and NMP national income, but plans to recover to about the NMP rates of 1965-1970 in the 1976-1980 plan. East Germany shows a generally sustained rate of growth achieved in 1965-1975 and planned for 1976-1980. Czechoslovakia and Hungary show a pattern of moderate decline over the 1965-1970 and 1970-1975 periods that is projected for the 1976-1980 plan in their NMP measures. The pattern of decline in GNP rates from 1965-1970 to 1970-1975 was also evident for Czechoslovakia, whereas Hungary showed only a slight change in rate (an increase) in the more recent period. By both the GNP and NMP measures Poland showed a sharp rise in tempo of growth from 1965-1970 to 1970-1975, but the

NMP planned average annual rate for national income in 1976-1980 calls for a sharp decline (in percentages, 1965-1970=6.0, 1970-1975=10.0, 1976-1980 plan=7.0 to 7.3). Romania increased its annual average growth rates from 1965-1970 to 1970-1975 steeply (GNP: 4.5 to 6.1; NMP: 7.6 to 11.2), and the NMP target for 1976-1980 calls for a continuation of the rate achieved in the 1970-1975 period. The high achieved and planned rates of Romania, Bulgaria, and Poland reflect their relatively lower level of development as compared to East Germany, Czechoslovakia, and Hungary.

Poland is something of a special case in the 1970-1975 period, when, following the fall of Gomulka, the policy makers under Gierek's leadership sought to mollify workers' resentment against steep increases in meat prices by keeping consumer prices relatively low and allowing real incomes to increase. Such a policy was made possible by foreign loans to finance both the growth of investment and consumption. The attempt to raise meat prices sharply in June 1976 again provoked workers' protests and the Polish government again had to modify its announced price policy.

The Polish experience no doubt has made an impression throughout Eastern Europe and the USSR. The Communist parties and their governments evidently feel that it is not enough that they proclaim to govern as representatives of the workers and peasants. They now have to reckon with rising expectations of the population. Stalinist duress, although modified after his death, has continued to be reflected by continued strong emphasis on high rates of investment vis-a-vis consumption, but this preference has been tempered by some recognition of the need to provide more substantial incentives in the form of consumer goods for the population.

Preliminary reports for 1976 growth on NMP national income produced (see Table 20) show most countries performing at substantially lesser rates than the average planned for 1976-1980 (Table 25). Poland reported a 1976 increase of 7.5 percent (vs 7.0-7.3 planned for 1976-1980), and Romania reports correspondingly 10.5 percent for 1976 (vs 11 percent planned for 1976-1980). The remaining four countries reported 1976 results within a range of about 1 to 2.5 percentage points below their average planned rates for the 1976-1980 period. Much of the shortfall in 1976 can be attributed to a poor year in agriculture, except in Romania (which experienced a very favorable increase of 17.2 percent in gross agricultural production as against a planned 1976 increase in the range of 15 to 27 percent) and in Bulgaria (which realized a 3.1 percent increase compared to a goal of 5 percent for 1976).<sup>21</sup> For the six countries of Eastern Europe as a whole gross agricultural production in 1976 increased by about 1 percent as against close to 6 percent planned.

Assuming more or less normal variation in weather over the 1976-1980 period, and barring major external complications, the 1976-1980 national economic plans for Eastern Europe appear achievable. The generally lower growth planned for this period seems to take into account the need to rely more heavily on growth of labor productivity and less on additions to the non-agricultural labor force than in the past.

<sup>21</sup> See the paper in this Compendium by Gregor Lazarek, "Comparative Growth and Levels of Agricultural Output and Productivity in Eastern Europe, 1965-1976," Table 24.

Future growth in Eastern Europe will depend strongly on demographic factors, application of advanced technology, attitudes of workers and managers toward production, the related state priorities as to incentives via real wage increases and investment alternatives, and changes in the complex system of economic organization and planning that affect personal motivations for increased work effort and innovative approaches to production. The degree of success in financing imports of advanced production technologies and the up-to-date machinery and equipment to implement them will be an important factor in future performance.

In assaying probable future economic performance in Eastern Europe, account has to be taken of current problems: growing labor scarcities, unsatisfactory rates of growth of labor productivity despite very high rates of investment, conflicting elements in the systems of planning, management, and measurement of performance, workers' apathy induced by policies of full employment that amount to feather bedding, or disguised unemployment, lack of adequate incentives to reward above average effort—a persistent problem in the socialized, centrally directed and overly regulated economies, rising consumer expectations based on increasing knowledge of the levels of living and consumer welfare in Western economies, inefficiency in production and disappointing technological progress resulting in considerable measure from insulation of domestic markets against foreign competition by state foreign trade monopolies and foreign trade price equalization measures, limited possibilities for wider participation in world trade because of dependence on Soviet sources of raw materials (oil, natural gas, iron ore, etc.), rising costs of imported raw materials, pressures to match the short work weeks achieved in Western industrialized countries, increased expenditures to protect the natural environment against pollution, dissatisfaction with the quality of production, continued housing scarcities, inadequate provision of consumer services—the list could be continued.

These problems are by no means peculiar to Eastern Europe, but they are exacerbated there by the expectations of the population encouraged by the claims of the socialist planners to catch up with and surpass the Western industrialized countries by measures of human welfare.

If one should judge economic progress by the changes in structure of national product and employment (expressed as shares of sectors of production in the corresponding national totals), then Eastern Europe has indeed taken great strides since the end of World War II. But growing shares of industry, construction, and services offset by declining shares of agriculture are approaching practical limits. Transfer of labor from agriculture to non-agricultural sectors still has further possibilities, more substantial in Poland, Romania, and Bulgaria than in the remaining countries, but compensation must be forthcoming in terms of increased provision of fixed capital and current inputs (fertilizers, insecticides, imported protein-rich feedstuffs, improved varieties of plant and animal breeding stock, improved agricultural technology, etc.) and in terms of incentives to agricultural workers (high wages or other forms of personal incomes).

Non-agricultural employment increases achieved by higher rates of participation, particularly of females, in the work force probably

have reached their practical limits in most of the countries. Some tendency toward declines may in fact be at work as the increase in levels of real incomes make it possible for women to give more time to child rearing and to spend more time in other home making activities.

Because of the inefficient use of labor in socialized enterprises that is fostered by the current system of centralized planning and direction of production, by the criteria for measuring performance of enterprise managements, by the overly egalitarian, redistributionist policies in respect to wages and such modest accumulations of wealth as have occurred in some countries (strictures against two cars per family, more expensive dwellings, etc., enforced by decrees of confiscatory taxation, in Poland for example), and by other negative motivational factors, there has been created a "reserve" of labor that can be activated by suitable government policies. To undo the disguised underemployment in the socialized economies would require measures that in essence, if not in form, would amount to substantial reprivatization of economic activity. With decentralization of management and direction of economic activity, with greater scope for local initiatives motivated by incentives for gain from extra effort on the job, fewer workers would be required for a given quantity of output. The workers that would have to be added under the present inefficient regimen of labor utilization in order to meet higher output goals in a given factory could be substantially reduced in number and the saving of labor could be made available to be used where genuine shortages occur.

In order to enhance labor productivity, the countries of Eastern Europe are striving to add new, technologically advanced machinery and equipment and production processes in industry and other production sectors. Depreciation rates had been set too low; nevertheless, the value of fixed capital whose "life" had expired continued to increase. In Hungary, in 1971, such "expired" fixed capital had risen to 51 percent of the total in industry and 22 percent in transportation and communications.<sup>22</sup> New, higher rates of depreciation have been set in Hungary, East Germany and other countries.<sup>23</sup> Investment priorities are being directed toward completion of unfinished projects and modernization of present facilities. Imports from Western countries of up-to-date technology and the equipment to implement it rank high in priority, but availability of foreign credits or payment by exports to the West set limits to such imports.

The present ferment of economic reforms and counter reforms continues in Eastern Europe. Their aim is to increase efficiency of production by appealing to the economic self interest of enterprises, managers, and employees, but this aim constantly confronts a cardinal principle: that the hegemony of the Communist parties in all areas of social, political, and economic life remains unchallenged. A generation of managers, scientists, technocrats, and workers that would have extensive freedom to follow their own views directed toward economic efficiency and innovation would be inclined eventually to favor a pluralistic approach to political issues, and could pose a challenge to the self perpetuating Communist party elites that regard government policies

<sup>22</sup> G. Gertsovich and B. Mihailov, "The Efficiency of Social Production in European CEMA Countries," *Voprosy ekonomiki*, No. 11, 1973, pp. 108-119.

<sup>23</sup> Polish rates scheduled for introduction in 1974 were higher by 43 percent in machinery and equipment and 34 percent in structures; see Z. Fedak, in *Finanse*, No. 6, 1973, pp. 1-12.

as their special prerogatives. That is why reforms have been piecemeal, on-again and off-again. Appeals, exhortations, and slogans purveyed by the government monopoly of the press and telecommunications and disseminated by party cadres strive to educate the population to acceptance of the Party decisions, but they are not always successful. The abrupt price changes in Poland under Gomulka and Gierek that had to be rescinded illustrate the gap between those who claim to govern in the name of the workers and the workers themselves. Although such confrontations have not been so evident in other East European countries, no doubt the possibilities have been considered by their ruling elites. Such consideration would tend to modify the ambitions of the Party leaders.

There are lessons to be learned by non-Communist countries from the experience of the East European countries. Economic progress can occur, indeed may be much more efficient, without socialization, centralization, and organized duress imposed upon the population. A transition to a state of affairs characterized by the countries of Eastern Europe can occur by foreign intervention, domestic coups, or continually increasing central government intervention in economic affairs. Government actions aimed at curing transient maladjustments tend to become institutionalized and self-perpetuating. Economic regulations and controls metastasize and eventually create an immense burden that is counterproductive as regards the initial humane impulse that started the process. Once instituted, a bureaucracy seeks to perpetuate itself, to grow, to defy efforts to eliminate it. Growth of central government bureaucracy requires a concomitant growth of a secondary bureaucracy serving business enterprises, local governments, and consumers in order to meet the growing demands for reports, counter reports, and adjudication of conflicts. The burden imposed upon society in terms of the direct support of the two bureaucracies is very substantial; in terms of its impact on efficiency, it may prove even greater. Decisions are delayed; efforts at optimization dependent upon knowledge of the situation on the lower levels are impaired.

The socio-economic transformations in Eastern Europe were brought about by Soviet intervention and by resort to "class war", pitting the have-nots against the haves, including middle and lower middle class farmers, businessmen, handicraftsmen, and professional people in the sector of services. A new class of the Party elite and government bureaucracy took over policy making in all aspects of social-political-economic life, and by detailed direction and control of activities this new class implements its policies. In the process, the scope and incentive for above average performance at the production level have been very substantially limited.

This limitation lies at the root of the problem of economic efficiency, productivity, and innovation in Eastern Europe. Very marked changes have occurred in the composition of national product by sector of production and by the corresponding sectoral distribution of employment. These changes, at least in percentage composition, put Eastern Europe relatively close to Western Europe. But these structural changes have not overcome the big gap in the levels of per capita productivity. After about half a century of socialized economy

in the USSR and close to thirty years in Eastern Europe, despite relatively great percentages of national product allocated to investment, Eastern Europe and the USSR still are seriously lagging in per capita output (see Table 10). Analysis of the causes of this lag necessarily would be complex, taking account of historical events, national characteristics, availability of natural resources, and institutional arrangements governing economic and social activity. But personal motivation—the impulse to work harder and more innovatively—would appear to be one of the most important factors in accounting for relative productivities. This factor is recognized throughout Eastern Europe; the problem is how to improve productivity given the present institutional arrangements.

Such is the situation that confronts the countries of Eastern Europe today. They are trying to find their way out of the mediocrity of performance that has been induced by socialization and centralization of planning, direction, and control over economic activity and by overly egalitarian and redistributionist policies regarding personal incomes and saving.

Other countries should take stock of where they are headed. Inflation is a species of class war; it destroys the purchasing power of savings made possible by productive effort and thrift. It propels the modest "haves" toward the position of "have-nots", reducing many who considered themselves adequately protected for retirement to becoming supplicants for government support. Moreover, it suggests to those aspiring to climb up the economic ladder that their efforts through harder work and thrift will prove in vain. The consequence for personal motivation should be clear: Why strive to make more than an average effort; perhaps a below average effort in the circumstances would be psychically more rewarding. Why save?

It is through the saving aspect that unwanted socialization and its likely consequences for personal motivation may appear. If private saving is inadequate to maintain and expand production facilities and finance innovation, then the burden must be borne via taxation by governments. The most likely corollary is that governments will direct and control what they have financed. Couple this with income leveling policies, and the outcome may not be unlike the situation that Eastern Europe is wrestling with today.

## VI. SUMMARY AND CONCLUSIONS

The statistical record of comparative economic structure and growth in Eastern Europe is given in the tables of this paper. Some summary conclusions are presented below.

1. The rate of growth of population in Eastern Europe as a whole has declined from about 10 percent over the 1955–1965 decade<sup>24</sup> to about 6 percent from 1965 to 1975 (Table 1). The average annual rates of increase of population in Eastern Europe in the 1970–1974 period have been at about the same level as in Western Europe. Labor shortages are evident in East Germany (which has the continued distinction of negative rates of population growth), Czechoslovakia,

<sup>24</sup> Based on national statistical yearbooks; see my tabulation in Thad P. Alton, "Economic Growth and Resource Allocation in Eastern Europe," in U.S. Congress, Joint Economic Committee, "Reorientation and Commercial Relations of the Economies of Eastern Europe," Washington, 1974, p. 255.

and Hungary. Annual rates of increase in total employment, 1970–1975, range from a low of 0.4 percent (Hungary and East Germany) to 2.5 percent (Poland). (See Table 22.)

2. The structure of production over the 1965–1975 period reflects the continued growth of the share of industry in GNP. The shares for industry have leveled off in Czechoslovakia and East Germany at about 42 percent, and in Hungary at about 34 percent. In the other countries the share of industry has continued to grow over this period, reaching in 1975 a range of from 36 to 39 percent of GNP. The shares of agriculture and forestry combined have fallen over the 1965–1975 period, and by 1975 they came within a range of 13.5 percent (East Germany) and 29.4 percent (Romania). (See Table 2.) Comparisons with Western Europe show the shares of industry in GNP (see Table 3) roughly comparable to those in Eastern Europe; the shares of agriculture in Western Europe were very considerably lower than those in Eastern Europe. Because of differences in coverage, the net material product (NMP) national income excluding various services included in GNP, and differences in valuation, the percentages in Tables 2 and 4 are not comparable. The sectoral shares in the material net product (NMP) national income produced (see official data in Table 4) present diverse compositions, depending on the bases of valuation. (E.g. in 1965, industry in Hungary accounted for 67 percent of the total in “comparable” prices, but only 42 percent in 1968 prices; in 1975, the industrial share in the Hungarian total was 45 percent in 1968 prices and 60 percent in current prices). The general impression of the leveling off of the share of industry in GNP given in Table 2 for Czechoslovakia and East Germany is also reflected in Table 4 in shares of NMP national income. In general, the share of industry in the NMP total is very considerably exaggerated by the inclusion of turnover taxes in the NMP of industry.

3. Domestic gross investment as a share of total GDP “domestically distributed” (including the import surplus) in 1974 in current prices in Poland was about 39 percent. (If the import surplus is considered both as a reduction of the GDP distributed and as disinvestment, then the share for gross investment falls to 34 percent.) Comparable shares for Hungary in 1974 as shown by official Hungarian GDP tables were about 35 percent based on the total product domestically distributed (and about 32 percent if imports are subtracted as for Poland above). The shares of gross investment for other countries in Eastern Europe were not calculated at this time, but they probably would fall in or close to the range shown by Poland and Hungary. Official NMP statistics of the composition of national income domestically distributed (Table 5) vary considerably for a given country depending on the prices used for valuation. For example, in 1966 in Czechoslovakia, the share of net investment was 16.5 percent in current prices and 20.6 percent in 1967 prices (Table 5); in 1975 in current prices the share was 28.9 percent. In 1975, the net investment share in Hungarian NMP national income distributed was 24.8 percent in “comparable prices” and 28.9 percent in current prices. In Poland, in 1975 net investment accounted for 37.8 percent of NMP national income distributed in constant 1971 prices and 35.1 percent in current prices. Rates for 1975 in Bulgaria and Romania were around 33 percent, but the price bases were not comparable.

Since the NMP concept excludes depreciation (which would raise the net investment to gross) and "non-productive" services, the percentages shown in Table 5 are not comparable to shares in GNP or GDP. On balance, however, adjustment to enlarge the NMP concept to GDP, as is available for Hungary (see above) would raise the percentage figure for investment considered as gross.

4. In 1974 the economically active population in the East European countries and the USSR comprised roughly one-half of the total population; in Western Europe and the United States the range was 35 to 46 percent (Table 6). The shares of non-material services in Eastern Europe and the USSR have risen from a range of 9 to 15 percent of the total economically active population in 1960 to a range of 15 to 22 percent in 1974. For Western countries, the corresponding 1974 range was from 18 to 34 percent. Shares of industry in the total economically active population in Eastern Europe have risen substantially from 1960 to 1974 and by 1974 were getting close to those in Western Europe, but the shares of agriculture in Eastern Europe, though declining sharply from 1960 to 1974, were in 1974 considerably above those for Western Europe. Table 7 provides details on the structure and growth of total employment, 1965-1975, by sectors of production. The shares for employment in industry increased slightly over the 1965-1975 period in Czechoslovakia, East Germany, Hungary and Poland, but increased sharply in Bulgaria and especially in Romania (from 19 to 30 percent). Agriculture's share in the growing totals declined relatively and in absolute numbers as well. Table 8 provides details on the composition and trends in employment in industry by branches (machinery, chemicals, etc.) over the 1960-1975 period. Machinery, the largest sector in 1960, had increased its share further by 1975. By 1975, in terms of the share of machinery in total employment in industry, the countries of Eastern Europe were getting to be more similar than in 1960.

5. Table 9, showing the structure and indexes of growth of fixed capital in Eastern Europe reflects the growing importance of industry. Fixed capital grew rapidly in all countries, but some reservation is warranted concerning the data for Bulgaria and Romania, where there is reason to expect some inflation of the rate of growth (data are evidently in current prices for Bulgaria and perhaps for part of the time period covered for Romania—see Notes to Table 9 in the Appendix).

6. The 1975 GNPs per capita in 1975 U.S. dollars in Eastern Europe are estimated in Table 10 roughly within a range of about \$2,200 (Bulgaria) to \$3,700 (Czechoslovakia and East Germany), and in non-CEMA countries within a range of \$2,500 (Greece) to \$6,800 (West Germany). The comparable figure for the United States was \$7,100. There is considerable room for refinement with a view toward comparability in such dollar estimates. Though rough, these figures indicate relatively low productivity in Eastern Europe, even though the national composition of total employment there is becoming close to that in Western countries.

7. Tables 11, 12, and 13 present our indexes of total real GNP, real GNP per capita, and GNP by sector of production, 1965-1975. Official measures of NMP national income produced, total and per capita, are shown in Tables 14 and 15. The GNP and NMP indexes

are not comparable with respect to coverage and bases of valuation, and one should therefore expect differences in the rates of growth they show. Indexes of real GNP per capita 1965-1976, Table 12, show growth within a range of 34 percent (Hungary) to 66 percent (Romania). The NMP measures per capita (Table 15) range from a growth of 76 percent (East Germany) to 142 percent (Romania). Notes to the tables should identify the price bases and linkages of segments of the NMP indexes and the methodology and weights of our GNP measures. Table 13 shows our GNP indexes overall and by sector of production, 1965-1976. Construction, trade, transport and communications, and industry are the faster growing sectors, but their rank varies from country to country. Agriculture grows less rapidly than overall GNP in all the countries of Eastern Europe. Table 14 details the growth of NMP, 1965-1976, overall and by sectors. The general impression as to which sectors are the faster growing ones is about the same as that conveyed by Table 13, but of course the rates differ from those in Table 13 because of different bases of valuation and methodology. The Appendix, Notes to Tables, provides background on this matter.

8. Indexes, 1965-1975, of NMP national income domestically distributed (Table 16) show net capital formation (accumulation) growing faster than the remaining major component, consumption. The sub-component, personal consumption, grows less rapidly than the "other" (collective) consumption.

9. Average annual rates of growth, 1965-1976, per capita of GNP (Eastern Europe) and GDP (other countries) are shown in Table 17. The overall impression, taken as a simple unweighted arithmetic average for the 1965-1970 period, is that the non-CEMA countries grew much more rapidly (5.1 percent) than the East European countries (3.2 percent). The United States and Great Britain grew more slowly than the other indicated countries. The 1970-1975 period was more favorable for Eastern Europe vis-a-vis the other group of countries. The less developed countries in both groups show faster rates of growth. (Japan was the significant exception.)

10. Average annual rates of growth of GNP by sectors of production 1965-1976, are shown in Table 18. These rates confirm the overall impression given in Table 13 (see item 7, above). Trade, construction, transportation and communications, and industry, with varying rank among countries and subperiods, are the faster growing sectors. Agriculture grows more slowly than overall GNP. Housing and government services also grow at below average rates.

Tables 19 and 20 show average annual rates of growth of NMP national income produced 1965-1976, per capita, overall, and by sectors of origin of product at constant prices. The rates in Tables 19 and 20 are in general higher than for correspondingly named sectors of GNP in Tables 17 and 18, but this should be expected, given the differences in coverage, bases of valuation, and methodology of calculation of the underlying indexes.

The obviously weird rate of growth for the trade sector in Romania (a negative annual average rate of growth of 21 percent over 1965-1970) probably is a manifestation of price equalization activities on foreign and/or domestic trade account, and it by no means reflects the actual, customary services rendered to the population as gauged

by trade turnover. However, it appears that the indicated negative growth of the official trade NMP index is incorporated into the overall NMP index of national income produced and lowers the rate of growth of overall net material product. Other countries of Eastern Europe at various, mostly earlier periods (e.g. Hungary) would seem to have had a similar experience. The unfavorable impression created by such a measure has been dealt with in Romania by not publishing the detailed index after 1970; in other countries the phenomenon may have been corrected by changes in methodology for dealing with price equalization differences on foreign trade. It would not appear, however, that such changes would be carried back uniformly retrospectively, but that the adjusted measure simply would be linked to the previously published NMP measure.

11. The annually detailed indexes underlying Table 16 are expressed as average annual rates of growth of NMP national income domestically distributed, 1965-1975, in Table 21. The NMP domestically distributed differs from the NMP national income produced by the extent of the import or export surplus and losses of product. For the overall 1965-1975 period, net capital formation in each of the five East European countries shown in the table grows faster than total consumption. Personal consumption, a component of total consumption, grows more slowly than the total; this implies that collective consumption grows more rapidly than total consumption. The general impression by subperiods, 1965-1970 and 1970-1975, is roughly the same as for the overall 1965-1975 period, but with two exceptions: consumption in East Germany and Hungary in 1970-1975 grew faster than net capital formation. Romania does not publish annual indexes of national income distributed.

12. Average annual rates of growth, 1965-1975, of employment and labor productivity with respect to GNP are shown in Tables 22 and 23. Poland ranks first in rates of growth of employment, and East Germany and Romania rank last. Variation over the subperiods 1965-1970 and 1970-1975 indicated a leveling off or reduced rates in most countries. Bulgaria is an exception here. An examination of participation rates (number of persons per 100 of relevant total population) shows such rates rising in most countries of Eastern Europe and the USSR from 1960 to 1974, to about 50. Participation rates for women have increased substantially in Eastern Europe. Participation rates in countries of Western Europe have declined from 1960 to 1974, and are substantially lower than in Eastern Europe (a range in 1974 of 35.4 in Italy to 46.3 in Great Britain). U.S. participation rates have risen from 39.0 to 44.1 in this period.

Labor productivity with respect to GNP in 1970-1975 in Eastern Europe has grown on the whole somewhat faster than in 1965-1970; Bulgaria is an exception here, showing a small decline. Labor productivity rates in industry declined in 1970-1975 as compared with 1965-1970 in all countries except Hungary and Poland (see Table 23).

13. Table 24 summarizes indexes of NMP national income produced, employment, fixed capital, labor productivity, capital productivity, and capital per unit of labor, 1965-1975, for the material product sphere as a whole and for major sectors of material production. A comparison of the increases of labor productivity 1965-1970 versus 1970-1975 presents a mixed picture by countries and sectors of pro-

duction: The table presents a general impression of the trend in overall labor productivity (i.e., with respect to NMP national income) as declining in Bulgaria and Czechoslovakia, leveling off in East Germany and Hungary, and rising in Poland and Romania.

14. A general impression of the prospects for 1976–1980 in comparison with the actual and planned performance in 1971–1975 is presented in Table 25. With the sole exception of Bulgaria, all the countries of Eastern Europe are planning for slower growth in their current five-year plans. The less developed countries have set higher goals than the more developed ones. Such partial information as the table supplies indicates that real gross fixed investment is expected to grow faster than real NMP national income produced. The planned rates of growth, 1976–1980, for total retail sales in real terms suggest a slower growth of total real consumption than of national income produced.

15. A review of economic performance in the 1965–1970 and 1970–1975 periods (Tables 18 and 20) taken in conjunction with plans for growth of overall NMP national income produced in 1976–1980, shows, with few exceptions, a generally declining trend from 1965–1970 to 1970–1975 and expectations of a return to the 1965–1970 rates in the current, 1976–1980, plans. Poland is something of a special case in the 1970–1975 period when, following the fall of Gomulka, the party and the government under Gierek's leadership reversed the Gomulka policy of price increases for meat, kept prices relatively stable, and achieved high rates of growth of overall real NMP, real consumption, and real gross fixed investment. This was made possible by import surpluses financed by foreign credits. Poland's plan for 1976–1980 calls for lower rates of growth, evidently in an attempt to live within her own means.

16. Assuming average weather conditions, and barring major external complications, the East European plans for 1976–1980 appear achievable. The planned growth rates seem to place less reliance on expansion of employment and more reliance on growth of labor productivity.

17. Future growth in Eastern Europe will depend strongly on demographic factors, priorities as to resource allocation to investment and consumption, and incentives to managers and workers to work harder and to introduce up-to-date technology by absorption of Western technology and by domestic innovations. Foreign credits may become less easily available than in the recent past and debt service is becoming a heavy burden.

18. Eastern Europe faces a broad array of economic difficulties: growing labor scarcities, unsatisfactory rates of growth of labor productivity despite very high rates of investment in plant and equipment, conflicting elements in the systems of economic management and control, workers' apathy induced by policies of full employment that result in disguised unemployment, rising consumer expectations, disappointing technological progress, rising costs of imported oil and other raw materials, continued housing scarcities, inadequate provision of consumer services—the list could be extended. These problems are not peculiar to Eastern Europe; other countries face such problems

as well. One of the major problems is personal motivation to work harder and to generate technological progress. It appears to be a consequence of the socio-economic-political system that tends to suppress personal motivation and opportunities for improving efficiency at the enterprise and local levels for fear of eventual confrontations by the new generation of technocrats and workers against the hegemony of the Communist Party elites in the sphere of setting national policy and controlling practically all aspects of social, economic, and political activity.

19. Although the countries of Eastern Europe are approaching a structure of economic activity close to that of Western Europe, productivity per capita in Eastern Europe seriously lags behind that of Western Europe (see Table 10). After about thirty years of socialist industrialization with exceptionally high rates of investment, the gap in productivity remains very large.

20. There are lessons to be learned by non-Communist countries from the East European and Soviet experience. Economic progress and rising human welfare do not require the duress experienced by the populations of Eastern Europe and the USSR. Indeed, such progress may be sounder and more efficient where personal motivation and local initiatives are not curtailed by overly detailed central direction and control. The major caution to be noted here is that overt class war supported by foreign intervention is not the only way to get into the difficulties that have been experienced by the populations of Eastern Europe and the USSR. Inflation is a species of class war; it destroys the purchasing power of savings made possible by productive effort and personal thrift. It propels the modest "haves" toward the position of "have-nots", reducing many who regarded themselves adequately protected for retirement by their savings to the near prospect of becoming supplicants for government support. Inflation suggests to those aspiring to climb the economic ladder to a middle class position that their efforts may prove futile. There may be greater combined proximate monetary and psychic rewards by making a less than average effort, but over the longer term, there will be less product overall to be shared. And, of course, inflation undermines incentives to save.

It is through this saving aspect that unwanted socialization and bureaucratic intervention in multiple aspects of life can appear. If private saving and investment should be replaced by government expenditure (financed in part by inflation, a form of taxation), then the government will no doubt seek to control the activities it finances. If this is coupled with strongly income leveling and redistribution policies, the adverse consequences for personal motivation, productivity, and personal consumption would not be unlike those of Eastern Europe.

#### APPENDIX

##### NOTES TO TABLES 4, 5, 14, 15, 16, 19, 20, 21, AND 24

Net material product figures in this report reflect East European "national income" measures that exclude government and a number of other services. Calculated as the gross value of output of the material sectors (at sales prices including turnover taxes) less material costs (including depreciation), net material product is not quite strictly a value added measure because small amounts of non-material costs, reflecting purchases by the material sectors of services, are not deducted and remain within the value of "national income produced."

The definition of what constitutes the material sectors for purposes of measuring net material product is not standard for all the countries under review, and for two countries it has not remained the same throughout the period covered in this report. Specifically, in the measures for East Germany, Hungary, and Poland, transportation and communications services are treated as material product in their entirety, whereas in Czechoslovakia only freight transportation and a portion of communications defined as "productive" enter into the material product. For Bulgaria and Romania, the NMP measures for the early years reflect definitions similar to that of Czechoslovakia, but as of 1970 for Bulgaria and 1971 for Romania, the definitions were broadened to encompass passenger transport, all of communications, and some other previously excluded services related to other sectors. The Bulgarian and Romanian indexes are chain linked at these years to provide continuity; retrospective data in the later coverage have not been published.

Constant price bases for the NMP measures also vary from country to country and are not in all cases the same throughout the period under review. Bulgarian indexes are based on prices of January 1, 1962 for the years 1965-1971 and linked to measures in January 1, 1971 prices for 1971-1976. Czechoslovak NMP data for 1965-1966 given in prices of April 4, 1960 are linked to data in prices of January 1, 1967 for 1966-1976. East German data are available in 1967 prices for the whole period, 1965-1976, Hungarian measures are based on 1968 prices throughout 1965-1976. Polish measures for 1965-1970 based on 1965 prices are linked to measures based on 1971 prices for 1970-1976. Romanian measures use 1955 prices for 1965-1966, linked to data in prices of 1963 for 1966-1976. Chain linking is the standard method for deriving continuous series.

NMP data by sector of origin, whether in constant or in current prices, include turnover taxes. It is the practice to include the turnover taxes in the NMP originating in the sector in which the taxes are collected. In all of the countries under review, the bulk of turnover taxes are collected at the point of sale of goods from industry, and the incidence of this tax in the NMP values for industry is higher than it is for other sectors.

Definitions of NMP used reflect the material product definition constraints applicable in the respective countries. NMP used may differ from NMP produced by the amount of foreign trade balances, losses, and other discrepancies; published data sometimes reflect reconciled accounts. Dividing lines between "personal" consumption and "other" consumption vary, and the reader would be well advised to consult the sources with care before undertaking international comparisons on this point. Constant price bases and linkages for the published indexes of NMP by use are believed to be the same as those described above for NMP produced, although this identity is not always explicitly stated in the sources.

#### NOTES TO TABLES 7, 8, 22, 23, and EMPLOYMENT DATA IN TABLE 24

Employment measures used in this report reflect annual averages except for data by major sector for East Germany, where the data refer to September 30 of the respective years.

The data cover civilian employment only. The official sources indicate that persons occupied full time in the armed forces and in political organizations are excluded. In other respects, however, the coverage is said to be comprehensive, including private activity in all sectors as well as collective farmers in agriculture.

Descriptions of employment accounting in the sources sometimes state that persons absent from work on leave with full pay are counted as employed. These data are thus not strict measures of labor inputs in terms of man-year equivalents. It should also be noted that leave provisions and the amount of time worked per man-year vary somewhat from country to country in Eastern Europe and have varied within given countries over the time period under review.

Where employment data are considered in the context of GNP measures in this report (Tables 8, 22, and 23), sectoral boundary lines are believed to match those of the GNP sectoral indexes, including, for example, all transportation and communications employees in these sectors for all countries. Where NMP measures are under consideration (as in Table 24), the division between material production and "nonproductive" services follows the definition underlying the official measures for the country in question. Thus for Czechoslovakia, employment in the material sectors excludes persons employed in passenger transportation and in the communications services officially deemed nonproductive. It should be noted that productive-nonproductive boundary lines in employment data have not been stable over the time period under review. In addition to changes related to

the broadening of the definition of material product in Bulgaria and Romania, there are occasional abrupt declines in the series for employment in "nonproductive" administration and scientific services. These seem to coincide with the transfer of personnel formerly affiliated with central ministries and institutes to affiliations administratively subordinate to production organizations, or from budgetary to *khozraschet* financing. Apparently, such transfers redefine the productivity of their employment.

The employment measures used in this report are based on absolute figures given directly in official statistical sources except for two countries. For Romania, absolute year-end figures were available for 1965 and 1970-1975; official indexes for 1964-1969 were used to obtain annual averages for 1965-1970. For Bulgaria, official annual averages in the desired employment coverage were available up to 1970. Our measures for the period after 1970 are estimates derived by assuming that the ratio of the growth of total employment to the growth of workers and employees (excluding collective farmers and private employment) would be the same over the 1971-1976 period as the average ratio indicated for 1965-1970. Total employment thus estimated was then broken down among sectors on the basis of official percentages on the structure of total employment given in Bulgarian yearbooks.

#### NOTES TO TABLE 9 AND FIXED CAPITAL DATA IN TABLE 24

Fixed capital data presented in this report reflect annual averages except as otherwise indicated in notes on Table 9. A possible exception is Czechoslovakia, for which the yearbook notes offer no statement as to the time reference of the data given.

All the figures used here refer to undepreciated values of fixed capital, variously termed "gross inventory value", "full purchase cost", etc. The sources suggest that it is generally the practice to include the value of surveying and other development and overhead costs, as well as direct costs of the assets.

Constant price data are not consistently available for all countries. The Bulgarian series at "full initial cost" are described as originating from a capital revaluation as of 1949, with subsequent additions "at the cost at which the fixed asset was put into operation and entered into accounting ledgers." This implies valuation at an accumulation of current prices of various years. The results of a capital revaluation in Bulgaria in 1974 have not yet become available. Romanian methodology for the period prior to 1970 is described in terms similar to the Bulgarian, although Romanian data for 1970 and later are cited as being in 1963 prices.

The coverage of the official fixed capital data for some countries has changed over the years. Bulgaria and Romania both appear to have added to the total coverage of capital in 1970 and 1971, respectively, when they expanded their definitions of material product to include more services; the sectoral boundary lines between "productive" and "nonproductive" fixed capital also, of course, changed at the time. The series shown in this report are from the most recent yearbooks except for Romanian 1965 and 1970 old classification data included for comparability of detail.

Where the data are considered in the GNP context in this report (Table 9), sectoral boundary lines have been adapted insofar as possible to match those of the GNP indexes. For Czechoslovakia, the "nonproductive" fixed capital in transportation and communications has been included in the sector as shown in Table 9. As noted on that table, all sectoral coverages are not strictly comparable: Data on capital in housing for Hungary and Romania include some other services; Bulgarian capital data for industry include forestry. Where the capital data are used in the NMP context (Table 24), the sectoral boundary lines conform to the official usage of the country in question. Thus the capital in Czechoslovak passenger transportation and communications defined there as "nonproductive" is accordingly excluded from capital in the material sectors.

#### NOTES TO TABLE 10

The GNP dollar estimates in Table 10 are based on Maurice Ernst's study (in U.S. Congress, Joint Economic Committee, "New Directions in the Soviet Economy," Washington, 1966, Part IV, Appendix A, pp. 911-912) as updated in the present paper. The estimates were obtained as follows: First, the GNP at current domestic prices in the various East European countries was converted to West German marks in 1955 by means of estimated purchasing power ratios

for components of GNP. Second, the values in West German marks so obtained were converted into United States dollars by means of estimated purchasing power parity rates for 1955 prepared by Milton Gilbert and Associates ("Comparative National Products and Price Levels," Paris, OEEC, 1958). Third, the 1955 United States dollar values were converted to 1975 dollars by the use of the United States implicit GNP price deflator. Finally, the East European GNP values for 1955 in United States 1975 dollars were carried forward to 1975 by our indexes of East European GNPs in constant prices, 1955-1975.

#### NOTES TO TABLE 13

The methodology and detailed documentation of the GNP measures in this report have been published in various Occasional Papers of the Research Project on National Income in East Central Europe (see bibliography). Summarized briefly:

Adjusted factor cost weights for each country were estimated as returns to labor (taken as payments to labor plus social security in each sector), plus returns to other factors, derived by distributing the remainder of total value added (at domestic market prices, for the economy as a whole) among sectors in proportion to the fixed and working capital in the respective sectors and the land in agriculture and by adding depreciation as officially accounted. A full description of sources and procedures will be found in OP-48, "Statistics on East European Economic Structure and Growth." Weights for Hungary in this report differ slightly from those in OP-48 because of the subsequent incorporation of more precise capital data in the estimates.

Sectoral indexes for major production sectors were derived from official physical output data, weighted for aggregation as appropriately as possible with domestic prices and value added by subsectors. For services except housing, the indexes are largely derived from employment. For housing, the basis is official measures of housing stock. For some countries, minor production sectors are also represented by employment, or by official value aggregates in constant prices. The indexes as they appear in this report reflect updating of those published earlier, with revisions in some instances in the light of later data and updated weight regimens. Changes since their most recent summary in OP-50, "Economic Growth in Eastern Europe, 1965-1975" (1976), will be documented in a forthcoming Occasional Paper covering 1965-1976.

#### BIBLIOGRAPHICAL NOTE

Western sources directly drawn on for this study are cited in context. East European official figures given are from the standard statistical yearbooks, periodicals and plan fulfillment reports of the countries in question and from the CEMA yearbook. For full citations of these sources, the reader may refer to the bibliography of our report on "Defense Expenditures in Eastern Europe, 1965-1976," in this volume.

The GNP indexes and structural measures presented reflect the cumulative work of the Research Project on National Income in East Central Europe, documented comprehensively in the Project's publications, which are as follows:

## I. INTRODUCTION

The present study aims to indicate the magnitude, trends and structure of military expenditures of selected countries of Eastern Europe: Bulgaria, Czechoslovakia, East Germany, Hungary, Poland, and Romania. Valuations are shown in current domestic prices and in current dollars. GNP is also calculated in constant 1975 dollars. In order to place military expenditures in perspective, they are shown in the context of values of GNP in absolute and relative terms, as well as in terms of average annual rates of change (Chapters II and III).

In international comparisons of shares of GNP devoted to defense expenditures, the factor cost structure would be preferable to that given in effective market prices. Nevertheless, factor cost approximations conventionally calculated would still fall short of an equitable standard of comparison in those cases where conscription results in diverse proportions of opportunity cost being paid to conscripts in

\*The present contribution is a revision and updating of the authors' "Estimates of Military Expenditures in Eastern Europe," prepared for US ACDA, by the Research Project on National Income in East Central Europe, at L.W. International Financial Research, Inc., N.Y., N.Y. The authors are indebted to Frank Bandor and Alice Mayer for cooperation in the preparation of this paper.

the form of nominal cash pay plus subsistence. This follows from the conventional procedure of accepting the market price (actual) returns to labor as equal to the factor cost of labor.

Where the concern is to compare internationally the shares of GNP allocated to defense, it would appear that a modified concept of GNP and military expenditures should be employed; that is, both the GNP aggregate and the military component should reflect suitable upward revaluation to account for services of military personnel at opportunity cost. We did not attempt such adjustments in the present study. It seems clear, nonetheless, that the outcome of such comparisons between countries of Eastern Europe on the one hand and the United States on the other would be to raise the shares of the former in relation to the latter.

Another approach to international comparisons of defense expenditures is to express all the outlays in a common currency. To this end we present estimated dollar valuations of East European military expenditures. In order to facilitate such conversions to dollars, we allocated the total military expenditures to personnel costs and other outlays, and used distinct conversion rates for the components (Chapter IV).

The results presented here are necessarily approximations. The procedures we employed could certainly be refined, particularly in getting better breakdowns of total expenditures, devising better conversion rates to apply to components of the total, making corrections for price distortions, and estimating the military expenditures outside and above the officially published defense budgets in each of the six East European countries reviewed in this study (Chapter V).

## II. GNP, DEFENSE EXPENDITURES, AND IMPLICIT CONVERSION RATES OF NATIONAL CURRENCIES TO DOLLARS

In this chapter we present for Eastern Europe as a whole and for each country, for the period 1965 to 1976, annual estimates of the total gross national product in current and constant dollars and total military expenditures in current dollars, conversion rates, and shares of defense in GNP. Given the limitations of time, accessible information, and material resources, we applied the best feasible methods of estimation available at present.

For each country the GNP values in current market prices in the respective national currencies were estimated as follows: Detailed independent estimates of GNP were made at our Research Project for Czechoslovakia for 1966 and 1967 and for Hungary for 1967 and 1968. Also rough estimates of GNP are available for East Germany for 1966 and Romania for 1968, for Bulgaria for 1968 and 1970. For Poland, detailed independent estimates of GNP are available only for 1954-1956, with rough estimates for the later 1960s. On the basis of the ratios between GNP and official national income (material product) for benchmark years, we were able to inflate the official national income series to the GNP concept for all other years covered in this study. It is to be noted that these ratios exhibited a degree of stability comparing the middle of the 1950s with the 1967-1968 period.

For purposes of this study, officially given military expenditures series are assumed to include the direct cost of maintenance of mili-

tary personnel, cost of military equipment and supplies, and maintenance of equipment and structures. In East Germany, expenditures for internal security are included in the military expenditures data. On the other hand, indirect military activity, i.e., expenditures on military research and development, industrial investment spending on military facilities, and a variety of other related spending are not included in the national defense figures. Some adjustments of official figures to conform somewhat more closely with the U.S. definition of military purposes are made in Chapter III.

The general level and relative importance of military expenditures in different East European countries may be obtained by expressing the defense outlays in percentages of the total GNP. Such a comparison will be meaningful only if the pricing of the defense and non-defense (civilian) components of GNP is uniform. Unfortunately, in all centrally planned economies, the prices of civilian consumption goods and services, because of the heavy incidence of turnover taxes, are relatively high in relation to prices of investment goods and, particularly, military hardware and other procurement items, on which turnover taxes generally are not imposed. Also, most probably, the production of defense items is heavily subsidized through the state budget. This uneven incidence of pricing results in substantial underestimation of the "real" cost of military spending when expressed as a percentage of GNP at market prices in domestic currencies (Table 1, column 6).

TABLE 1.—GNP, DEFENSE EXPENDITURES, AND IMPLICIT CONVERSION RATES OF EAST EUROPEAN COUNTRIES<sup>1</sup>

	GNP, millions of 1975 dollars	GNP millions of current dollars	Implicit conversion rate (\$=in domestic currency)	Indexes in current dollars 1965=100		Defense as per centage of GNP in

<sup>a</sup> Rates are based on least squares fit to  $1_n = 1_0 (1+r)^n$ . Data for 1976 are preliminary.

Sources: For East European countries, tables 1 and 6. For the U.S.S.R. and the United States, U.S.A.C.D.A., "World Military Expenditures and Arms Transfers", 1965-74 and 1966-75 issues; "Survey of Current Business," No. 2, 1977. U.S. Congress, Joint Economic Committee, "Soviet Economic Prospects for Seventies," 1973, p. 149; U.S. Department of Commerce, "Statistical Abstract of the United States, 1971, p. 242, and 1976, p. 327.

The conversion of military expenditures given in national currencies into current dollars is a very difficult task, given the lack of information on prices of military items and composition of military procurements in East European countries. Proper conversion, indeed, would require information on the composition of the forces, rates of military pay, the quantity, quality and technical characteristics of the various military items purchased in each year, and the value weights in the national currencies and in dollars. This study offers one approach to the problem of conversion. This approach is based on implicit conversion rates for GNP derived from comparisons of dollar estimates of GNP and domestic currency estimates of GNP, both given in current prices. Further refinements involve estimates of the structure of military expenditures, presented in Chapter III, with components then converted separately from domestic currencies into current dollars, as described in Chapter IV. All the conversion rates used, it should be said, rest on approximative methods and accordingly should be interpreted with caution.

In this study, the GNP dollar figures were first derived in constant 1975 prices on the basis of the 1975 GNP dollar values and then extended by GNP indexes shown by Alton.<sup>1</sup> The GNPs in constant 1975 dollars were then deflated into current dollars by the US GNP implicit price deflator.

The new estimates of defense spending (Table 1, col. 5 and Table 6, col. 1) value the East European (and the USSR) military personnel services directly in dollars at United States pay rates for officers and men, with some adjustments for quality. For converting the military nonpersonnel and research and development expenditures from domestic currencies into dollars we used the implicit average exchange rates (Table 1, col. 3) derived from comparisons of the esti-

<sup>1</sup> Thad P. Alton, "Comparative Structure and Growth of Economic Activity in Eastern Europe," in this volume, Tables 10 and 13.

mated GNPs in domestic currencies and the corresponding dollar values of the GNPs in current prices.

The important findings in Tables 1 and 2 may be summarized as follows:

1. The implicit conversion rates between East European domestic currencies and the US dollar decreased in the last eight years in most countries because the rate of inflation in the United States was higher than in most East European countries, especially in the 1970s.

2. Military expenditures expressed as percentages of GNP are substantially lower (in some countries several times lower, e.g., Bulgaria, Hungary, Romania) in domestic currencies than in current dollars. There are two reasons for these large differences: (a) the very low nominal pay rates in Eastern Europe for enlisted men (a small fraction of their opportunity costs), and (b) price distortions (the uneven incidence of turnover taxes, accounting profit taxes, and subsidies) which result in very low percentage shares for military expenditures in GNP at current market prices (as compared to shares on other bases of valuation, e.g., at dollar prices). Thus, these percentage shares of GNP in domestic currencies of centrally planned East European countries are very misleading for comparisons with percentage shares in other countries where such extreme valuation abnormalities do not occur (e.g. Western Europe, USA, Canada).

3. Our new estimates based on dollar valuations indicate that the percentage share of GNP spent on defense in Eastern Europe as a whole is more than double the corresponding percentage of GNP calculated in the national currencies.

4. When valued in dollars, the nonpersonnel and research and development expenditures (operations, maintenance, military procurements) expressed as a percentage of total defense outlays increased steadily from 37 percent in 1965 to about 44 percent in 1976. This would indicate a continuation of progress in mechanization and modernization of Eastern Europe's military forces.

5. Based on valuations in current dollars, defense spending grew at a somewhat slower rate than GNP (Table 2). In most of the countries defense spending grew at a slower rate in the 1965-1970 period than in the 1970-1975 period. For Eastern Europe as a whole, the average annual rate in the latter period was 10.6 percent, while that in the former period was 7.5 percent.

6. In all Eastern European countries except Poland, the nonpersonnel and R&D costs grew at substantially higher rates than personnel costs. The high annual percentage rates of growth of nonpersonnel costs observable in Bulgaria, East Germany, Hungary, and Romania over the last ten years apparently indicate rapid progress in mechanization and modernization of their armed forces.

7. Comparison of Eastern Europe with the USSR shows that the rate of growth of GNP was about the same in 1965-1975 in both regions and likewise the rate of growth of defense spending was about the same in both. The other Warsaw Pact member countries have contributed a lower share of their GNP's to defense than the USSR. In the last five years, however, the average annual rate of growth in military spending has been higher in Eastern Europe than in the USSR.

8. Comparison with the US, however, shows distinct differences. The average annual rate of growth of defense spending in current dollars from 1956 to 1975 has been significantly lower in the US than in the USSR or in Eastern Europe. The contrast is greatest for the 1970-1975 period, when the US GNP grew at an average annual rate of 9.4 percent, while the military expenditures grew only at 3.5 percent. The respective percentages for the USSR were 11.1 and 9.7, and for Eastern Europe, 11.9 and 10.6 (Table 2).

9. US military outlays on nonpersonnel and R&D costs in current dollars increased only 2 percent from 1970 to 1975. Since US wholesale prices increased by 58 percent in the same period, the nonpersonnel spending (operations, maintenance, military procurements, and research and development) actually declined by about 35 percent in real terms. This is in contrast to the continuous increase of these costs in the USSR and Eastern Europe in the same period.

10. In the NATO member countries (excluding the U.S. and Canada), defense spending accounted for only 3.7 percent of GNP in dollar valuation in the 1970-1975 period. Thus the NATO allies in Western Europe are carrying a disproportionately smaller share of the burden of NATO defense than the United States, which contributed 6.6 percent of GNP to defense in the 1970-1975 period.<sup>2</sup> Such a favored relationship did not exist between the USSR and the other members of the Warsaw Pact.

11. It should be noted that Eastern Europe as a whole currently spends, in terms of dollars, more on defense than any other country besides the U.S. and the USSR, or about one-fifth as much as the United States (see Tables 1 and 6). This is a significant contribution to the total defense expenditures of the Warsaw Pact.

12. One may conclude that the overall military posture of the Warsaw Pact countries has been steadily improving over the last ten years while that of the United States and other NATO countries has been deteriorating in relative terms. In other words, the United States and its NATO allies have materially reduced their military efforts, while the USSR and Eastern Europe continued to increase their military spending.

13. The tentative conclusions of this study point to the need for further research on comparisons of economic potential and related military expenditures.

The results shown in Tables 1 and 2 can be improved by detailed studies of the structure of the GNPs in current market prices and in prices with adjustment toward factor cost for all the countries under study, enabling corrections for major deviations from factor costs. Further research on exchange rates based on purchasing power parities is necessary for improving the international comparability of defense spending of various countries. Use of reliable purchasing power parity exchange rates could substantially alter the results shown here. A survey of currently used and alternative dollar conversion rates is provided in Chapter IV.

### III. ESTIMATES OF THE DEFENSE EXPENDITURES OF EAST EUROPEAN COUNTRIES BY MAJOR PURPOSE, IN CURRENT DOMESTIC CURRENCIES

The estimates presented in Table 3 offer a breakdown of direct defense budget expenditures between outlays to support uniformed military personnel and those for operations, maintenance, and procurements as a residual category that could not be further subdivided except on an arbitrary basis. In addition, some rough measures to reflect presumed research and development of a military nature financed outside of budget defense appropriations are offered for the three countries in which such activities may reasonably be thought to be greater than negligible.

<sup>1</sup> Data for 1976 are preliminary.

<sup>2</sup> Defense budget data for Bulgaria have not been published since 1970. Expenditures for 1971-75 are estimated as 6 percent of total planned budget outlays, the approximate share they accounted for in 1966-70. For 1976, in view of major changes in the budget structure, the estimate is based on 12 percent of total planned outlays excluding outlays on the national economy.

<sup>3</sup> Excluding the civilian portion of internal security.

Source: "Estimates of Military Expenditures in Eastern Europe," *op. cit.*, and notes thereto, revised and updated to 1971-76.

The concept of "military purpose" providing the underlying framework for these estimates is fairly strict. The intention is to reflect current outlays to support, equip, and administer armed forces, plus research and development directly related to military purposes. No attempt has been made to assess industrial investments that may be related to armaments production. Nor has any attempt been made to include here various military related outlays known to be financed outside the defense budgets proper, such as benefits to soldiers' families and paid leave for reservists. Investment expenditures made directly by ministries of defense, however, are implicitly included.

The definition of armed forces followed for these estimates includes, in addition to the regular army, navy, and air forces, the border guard troops routinely organized and equipped as army units in all these countries, and the security troops that are essentially military in their organization and equipment. It is important to distinguish between these latter, the "militarized police," and the various other internal security units, such as the secret police, the workers' militia, customs guards, prison guards, and other uniformed services that do not seem to be directly military in their organization and potential. This "civilian" portion of internal security is excluded from the estimates. Adjustments have accordingly been made in the budget expenditure totals for East Germany, whose published budget appropriation figures reflect defense and internal security taken together.

The general estimation method followed was the same for all the six countries covered. Working from estimates of regular forces and "paramilitary" border and security troops published by the Institute for Strategic Studies, London, and ACDA, the pay and subsistence of these forces were calculated with reference to national wage rates and consumption data. Exact procedures varied somewhat with the availability or non-availability of data or other evidence of national differences in structure. The resulting personnel costs were then deducted from the defense budget expenditure totals to obtain the estimates for operations (including civilian personnel and other administrative expenses), maintenance and procurements (other than supplies for the subsistence of uniformed personnel). The bases for the research and development estimates were budget expenditures on "science and research", of which only a portion were deemed "military". Again, varying availability of data necessitated some differences in method.

Inevitably, these estimates must be regarded as rough approximations. Many choices underlie them, some involving no small element of arbitrariness. For this set of estimates, we have continued to treat all paramilitary forces (border guards, security troops) as though they were financed out of defense budget appropriations uniformly in all countries. There is, however, increasing evidence that in some cases they are supported by the budgets of other, non-defense, ministries. Our personnel cost estimates may thus include manpower that is not actually paid for out of nominal defense appropriations. To the extent that this is so, it would simply mean that our estimates of nonpersonnel costs, derived as residuals from the official defense budgets, are too low.

The general results for all countries show a clear tendency for total defense expenditures to rise more rapidly than personnel costs. The rise in personnel costs, it should be noted, is partly attributable to the fact that rising wage levels and rising costs of living are reflected in our estimates of pay and subsistence. The numbers of personnel have tended to increase somewhat in very recent years, according to the Institute for Strategic Studies estimates. Increasing costs of operations, maintenance and procurements per uniformed effective are, of course, a logical concomitant of modernization, the introduction of more sophisticated and more expensive weaponry, communications and other equipment.

With regard to the changing structure of the observed defense budgets, it seems important to state that none of the breakdowns of expenditure by purpose in these estimates rely directly on the technique of estimating by analogy with other countries or earlier time periods. In the Benoit-Lubell estimates, analogy to Poland is the basis for all the countries in question but Czechoslovakia, and their sources suggest that their detailed breakdown of the residual after personnel costs for both countries derives from estimates made for 1956.<sup>3</sup> In the estimates presented here in Table 3, the technique of analogy was almost totally confined to minor aspects, such as differentials between enlisted men's and officers' pay.

No structural rule of thumb was applied to all in common beyond the assumption with regard to financing paramilitary troops, discussed above. The broad results are the product of numbers of troops and rates of pay and subsistence calculated separately for each country. No reasonably sound up-to-date basis was found for a breakdown of the operations-maintenance-procurement residuals, hence no new attempt was made in this regard.

#### IV. DOLLAR ESTIMATES OF EAST EUROPEAN MILITARY EXPENDITURES BY MAJOR PURPOSE, AND EXISTING CONVERSION RATES

For international comparisons of military expenditures, or of other components of national products of the Warsaw Pact countries, it is necessary to express the given values in the national currencies in a common unit of value. The present chapter will survey various available approaches for conversions into United States dollars and describe the alternative used for the estimates in this report.

Among the available conversion rates are two sets of official exchange rates and two sets of Western conversion rates applied to military expenditures. For each country, the official rates are the "basic" rate that is used as a unit of account in foreign trade statistics and the "non-commercial" or tourist rate applied to travellers' funds and sometimes to other personal transactions. The two sets of Western rates are, first, those estimated by Benoit and Lubell and subsequently adopted as the basis for dollar estimates published by the Stockholm International Peace Research Institute (SIPRI) and the Institute for Strategic Studies, London (ISS), and second, those used for dollar estimates published by the U.S. Arms Control and Disarmament Agency (ACDA) for 1960-1970.<sup>4</sup> A complete set of our rates for 1965-1976 appears in this study in Table 1, column 3. Various rates for 1975 shown in Table 4 were chosen for purposes of comparison with the original Benoit-Lubell estimates, which referred to 1964/1965. For all countries, our conversion rates are higher than the Benoit-Lubell rates. For 1975 our rates are close to the tourist rates for Czechoslovakia, Hungary, and Romania.

<sup>3</sup> Emile Benoit, ed. "Disarmament and World Economic Interdependence," New York, Columbia University Press, 1967, pp. 31-32 and 37.

<sup>4</sup> These rates were calculated for ACDA by Thad P. Alton, Gregor Lazarcik, Laszlo Czirjak, and Elizabeth Bass at the Research Project on National Income in East Central Europe, L.W. International Financial Research, Inc., New York, N.Y.

TABLE 4.—MAJOR AVAILABLE SETS OF RATES FOR CONVERTING EAST EUROPEAN NATIONAL CURRENCIES TO U.S. DOLLARS

Country	Official rates		Ours		Benoit-Lubell
	Basic 1975	Non-commercial (tourist) 1975	1975	1965	1964-65

Sources: Cols. 1 and 2: "Eastwest Markets," 1975, Chase World Information Corporation, New York, 1975. The rates are averages of 12 mos. Cols. 3 and 4: Table 1. Col. 5: Emile Benoit, ed. "Disarmament and World Economic Interdependence," New York, 1967, p. 40.

Of the two sets of official rates, it may be said that neither offers a satisfactory basis for converting military expenditures. The arbitrary nature of the "basic" rates is well known; indeed, it is admitted that they bear no meaningful relationship to purchasing power parity with respect to the goods moving in international trade. The noncommercial, or tourist rates, in contrast, are intended to and apparently largely do reflect purchasing power parities for a tourist's basket of consumer goods and services. Here, however, the objection is that such purchases not only represent a product mix lacking many of the elements included in military expenditures, but also that they are made at prices including a high incidence of turnover tax, from which purchases by East European ministries of defense are thought to be largely exempt, and probably higher profit rates than the average included in the prices of military procurements.

The Benoit-Lubell rates, in the words of their authors, represent "very rough purchasing power parity".<sup>5</sup> The rather general account provided of their derivation indicates that they are based on comparisons of general national income and product aggregates. It is not clear whether or not any consistent effort was made when deriving these estimates to allow for the skewed incidence of turnover tax and profits in East European prices of different categories of goods and for different categories of buyers. The authors were, however, quite aware of this problem, as evidenced by their use of differential rates for various components of the USSR's defense expenditures.<sup>6</sup>

The set of rates hitherto used for dollar estimates published by ACDA were given implicitly by estimates of GNP in national currencies and in dollars, with adjustments to remove the turnover tax and profits and profit taxes from the national currency values. These elements are believed to be absent in the prices paid by ministries of defense in Eastern Europe. The conversion rates thus derived must also be regarded as very rough approximations of purchasing power parity.<sup>7</sup>

<sup>5</sup> Emile Benoit, ed. "Disarmament and World Economic Interdependence," New York, 1967, p. 40.

<sup>6</sup> Specifically (in rubles per \$1 US): 0.5 for procurements, R&D, operations, maintenance, and construction; 0.2 for cash pay of military personnel and cost of transfers; 1.0 for military subsistence; see Benoit, *op. cit.*, p. 40.

<sup>7</sup> Details on these rates will be found in "Estimates of Military Expenditures in Eastern Europe," *op. cit.*, Notes to Table 1.

Clearly, the rates implicitly given by comparisons of aggregates in national currencies and in dollars are far from ideal. They reflect the roughness of the basic estimates. However, more satisfactory information on purchasing power parities is thus far fragmentary. Some work in this field has been done among the East European countries themselves, but very few results have been published. Joint efforts by the United Nations, the World Bank, and the International Comparison Unit of the University of Pennsylvania recently produced a study on purchasing power parity conversion rates for ten countries, including Hungary.<sup>8</sup> For 1970, this study gives an overall GDP conversion rate to one U.S. dollar of 13.4 forints in Hungarian weights and 19.8 forints in U.S. weights. Our implicit GNP conversion rate is 21.9 forints for 1970. Unfortunately, the UN study does not give separate conversion rates for military end items.

Even if detailed purchasing power parity rates were available for application to the diverse bundles of military goods and services, there would still remain problems of choosing suitable weights for combining the detailed rates into rates appropriate for major components of military expenditures. The composition of the latter varies among countries and, for given countries, over time.

The new estimates offered in this chapter represent a somewhat more direct approach to the problem of converting East European military outlays into dollars, although they still, inevitably, rest in part on rates implicitly derived from GNP estimates in dollars and in national currencies. The roughness of the "purchasing power" parities underlying the dollar figures has already been noted. Our approach is to convert the military personnel costs within military expenditures by pricing the "products", that is, the services of the officers and enlisted men, directly in American prices. This is done entirely in terms of U.S. cash pay rates including allowances (Table 5). The reliance on implicit GNP rates is thus somewhat reduced in scope.

TABLE 5.—PAY RATES IN THE U.S. ARMED FORCES

[Basic pay including allowances in current dollars, as of June 30 of each year]

<sup>8</sup> Irving B. Kravis, Zoltan Kenezsey, Alan Heston, Robert Summers, "A System of International Comparisons of Gross Product and Purchasing Power," Baltimore, Johns Hopkins University Press, 1975, p. 191.

Our results in current US dollars are presented in Table 6. The calculations are summarized below. We assumed that the percentage of officers in total military personnel was roughly the same as in the United States, or about 12 percent on the average for 1965-1970. We use this average for the East European countries for 1965-1976.<sup>9</sup> It may be noted that this ostensibly differs from the procedure in Chapter III where, for calculating the cost of military personnel in domestic currencies, we put the number of officers at about 20 percent of the total military personnel. This larger share was assumed to include lower grade officers, covering sergeants as well as commissioned officers.

<sup>1</sup> Data for 1976 are preliminary.

<sup>2</sup> Nonpersonnel costs include research and development costs.

Source: Calculated from "Estimates of Military Expenditures in Eastern Europe," op. cit., table 5, revised and updated for 1971-76.

In our calculations we estimated separately three functional categories of military expenditures: (1) personnel costs, broken into compensation for officers and for enlisted men, separately; (2) costs of operations, maintenance, and procurements; and (3) estimates of military research and development for those countries in which this category was believed to be of some significance (i.e. Czechoslovakia, East Germany, and Poland).<sup>10</sup> It is to be noted that military subsistence (cost of food and clothing) is included in compensation of officers and enlisted men in the dollar valuations.

Specifically, the estimates of different categories of outlays in current US dollars were done as follows: (1) The cost of personnel was obtained by attributing to officers in all East European countries (12 percent of total military personnel) the average yearly compensation in dollars of officers in the United States forces, and by attributing to the enlisted personnel in all East European countries (88

<sup>10</sup> Research and development is shown together with nonpersonnel costs (operations, maintenance, and procurements) in the table.

percent of total military personnel) 75 percent of the average yearly compensation (including subsistence) in dollars of enlisted men in the United States forces (Table 5). This rough downward adjustment of enlisted men's pay is justified by the consideration that the technical qualifications required of these men in Eastern Europe are assumed to be lower than in the United States. No similar downward adjustment was felt to be necessary for the officers' pay in Eastern Europe because their duties and competence are thought to be about the same as in the United States.

The average annual pay given in Table 5, columns 1 and 3, was multiplied by the number of officers and enlisted men for each country and year, respectively. The resulting values in US dollars are shown in Table 6, column 2, for officers and enlisted men combined.

(2) Dollar estimates of outlays on operations, maintenance, and procurements, and research and development (Table 6, column 3) were obtained by converting our estimates in domestic currencies for East European countries (Table 3, columns 5 and 6) by the GNP implicit average exchange rates between the US dollar and domestic currencies given in Table 1, column 3, for respective countries and years. These GNP exchange rates were derived by comparing GNPs in domestic currencies with the corresponding dollar values of the GNPs in current prices. The calculation of GNPs in constant and current US dollars is described in Chapter II, and the respective values are given in Table 1, columns 1 and 2. It is to be noted that the GNP dollar estimates in Table 1 are based on Maurice Ernst's study,<sup>11</sup> updated by Thad P. Alton.<sup>12</sup> The estimates were obtained as follows: First, the GNP at current domestic prices in the various East European countries was converted to West German marks by means of estimated purchasing power ratios for individual components of GNP. Second, the values in West German marks so obtained were then converted into US dollars by means of estimated purchasing power parity equivalents for 1955 prepared by Milton Gilbert and Associates.<sup>13</sup> Third, the 1955 US dollar values were converted to 1975 US dollars by using the implicit GNP price deflator. Fourth, the 1975 US dollar values of East European GNPs for the year 1955 were carried forward into the 1965-1976 period by East European GNP quantity indexes, and, fifth, the GNPs in constant US dollars of 1975 were deflated into current dollars by the US GNP price deflator.

It should be also noted that the estimates of military research and development outlays are very rough and were made only for Czechoslovakia, East Germany, and Poland, on the basis of very scanty information.

## V. CONCLUSIONS AND PROBLEMS

The preliminary findings on defense expenditures of East European countries presented in this brief study in national currencies and in US dollars are very tentative and very narrowly defined. They are based solely on the officially published budgets of the respective

ministries of defense in these countries. No attempt was made in this study to measure the defense effort of the East European countries more comprehensively along the lines of the definitions and coverage in usage in Western countries, particularly in the United States. Only a token adjustment in the direction of more comprehensive coverage was made by a small, very roughly estimated allowance from the state budget for science and technology that we assigned to military research and development in Czechoslovakia, East Germany, and Poland. These three countries are known to be developing and producing certain up-to-date armaments for the Warsaw Pact countries. Beyond this small R&D allowance, no attempt has been made to include here various military and military-related expenditures known to be financed outside the defense budgets proper, and not identified explicitly as part of the defense outlays in the official statistics of these countries. More specifically, the omitted items of military character financed partly or fully by ministries and agencies other than the ministry of defense in East European countries include:

1. Certain military units, such as border guards, security troops, construction troops, and transport troops, that may be financed partly or fully from the budgets of the ministries of internal affairs, ministries of security, ministries of construction, ministries of transport, or some agency other than the defense ministry.

2. Paid leaves to reservists while on military exercises, which are as a rule financed by the reservists' civilian employers from their own funds.

3. Severance pay to conscripts for several weeks at the beginning of their military service, financed by their civilian employers.

4. Costs of travel of conscripts and reservists to and from the place of military service, exercises or training, which may be borne by the transport ministry or local governments.

5. Costs of premilitary training, which is heavily stressed in all the East European countries, and may be borne partly or fully by the education ministries or local governments.

6. Costs of the transportation of troops and military equipment and the cost of communications for armed forces, which may be partly borne or subsidized by the ministries of transport and communications.

7. All or a part of the costs of civilian employees and supporting personnel in the military establishment, which may be financed from the budgets of agencies of the central administration other than the defense ministry proper.

8. Costs of support to soldiers' families, which may be financed partly or fully from the budgets of the ministries of social welfare or local governments.

9. Costs of pensions and disability pay for military personnel, which in many instances may be borne partly or fully by the ministries of social welfare, local governments, and former civilian employers of the soldiers, rather than by the defense ministry.

10. There is some evidence that certain military investment may be financed partly or fully by the respective ministry of construction or other economic ministries or industrial associations.

11. The cost of some of the military armament procurement for national defense may be partly or fully absorbed by the appropriate production association or ministry and ultimately settled through

transfers at the association level or by subsidies from the non-defense part of the state budget.

12. Imports of military end items may be financed partly or fully through the ministry of foreign trade price equalization funds or by other channels of financing and not directly from the budget of the ministry of defense.

13. There are direct references in official gazettes and collections of laws of East European countries concerning the pricing and price regulations that state that the purchases of the ministry of defense are not subject to the general regulations and that the defense ministry can set its procurement prices directly or by a different set of regulations. The implication of this differential pricing procedure is that the prices which the ministry of defense pays may be far below the costs incurred by the production enterprises. Differences between production costs and the prices paid by the military may be covered by subsidies from non-defense agencies in the state budget. The value of production and price subsidies channeled from the state budget to production associations and enterprises is very large in East European countries. Such subsidies could cover a substantial part of the cost of military procurement, and this would not be shown in the published budget expenditures of the ministry of defense.

The above indicated items, which are either definitely known to be excluded from the official published defense budgets or which are believed very probably to be in fact so excluded do not exhaust the possibilities. However, they illustrate a broad range of military-related expenditures that are or may be financed outside of the regularly published defense budget. If these expenditures are added together, their sum could be very large. To illustrate the order of magnitude which may be at stake, let us assume that the prices paid by a ministry of defense for all its purchases are about one-third below the cost of production. Since the nonpersonnel costs and subsistence valued in national currencies account for about 90 percent or more of the officially given defense budgets of most East European countries, this would require a 45 percent increase in the present defense budgets to enable the ministries of defense to pay the full cost of their purchases and meet also the present level of military cash pay. It may well be that the ministries of defense purchase many items at even lower prices than our assumed one-third discount.

We are not at present in a position to calculate the order of magnitude of the above enumerated items that should be included in the defense expenditures of the East European countries in order to make their defense outlays comparable with those of Western countries and the United States, in particular, and we refrain from speculation on the magnitude of such outlays. To provide good estimates of the more important military expenditures not included in the official East European defense budget would require a substantial and sustained research effort. Such an undertaking would examine in detail the intricacies of fiscal and other financial flows of the economies of Eastern Europe. Eventually it should place the comprehensive military outlays of Eastern Europe in proper perspective. The outcome of such an inquiry should be of paramount interest to United States policy makers and serve as background for ongoing negotiations on arms limitations and disarmament.

Research upon the complex problem of the extent of military expenditures and their channels of finance in Eastern Europe is a desirable task for the future. We would hope to be able to improve upon the work presented here. In the meantime, the present paper provides a general picture of the extent, allocation, and trends of defense expenditures in national currencies and in U.S. dollars based on the narrow definition and incomplete coverage of the official defense budgets of the East European countries. This limited approach provides only a sharply circumscribed impression of the military expenditures of these countries.

The military effort of the six East European countries covered in this study is indeed substantial: their number of regular active, well disciplined forces amounts to more than one-half of that of the United States. Even in terms of the narrowly defined official defense budgets, the military expenditures of the six East European countries as a group amount to about one-fifth of the total defense outlays of the United States in terms of U.S. dollars.<sup>14</sup>

## I. INTRODUCTION

During the last decade, the agricultural sectors in the East European countries have made significant progress. A series of economic reforms designed to increase incentives and efficiency, during the second half of the 1960's, resulted in an accelerated increase in the real income of the population. Increasing real incomes, in turn, brought rapidly rising demand for more and better quality foods of animal origin in the 1970's. In some of the East European countries, the domestic food supply did not keep pace with the growing demand.

In order better to satisfy the rising demand for high protein foods, the East European countries have taken a series of important decisions with regard to agriculture over the course of the last ten years. The results of these may be outlined as follows: (1) imports of feed grain, oilcake, fish meal and other high protein feed for livestock have increased sharply since the second half of the 1960's,<sup>1</sup> (2) an expansion of domestic production of high yield varieties of feed grain, concentrates, and roughages has been implemented in varying degrees of intensity in all East European countries, (3) a continuously larger flow of inputs in the form of fertilizers, increased mechanization, improved feeding technology, higher yield livestock breeds, better crop varieties

<sup>1</sup> See U.S. Department of Agriculture, Economic Research Service, "The Agricultural Situation in Eastern Europe," 1976, pp. 8-9.

may be observed, and the general improvement of agricultural technology has been receiving greater attention, (4) as part of broader economic reforms, a series of incentives to increase farmers' productivity have been continued in the form of higher prices for agricultural products, stimulation of personal interest through profits, greater participation of individual farm workers in management of farms, substantial increases in fringe benefits, and other personal incentives designed to encourage rational use of resources and improve agricultural productivity.

In Poland and Yugoslavia, meanwhile, the ownership and management of farms continues overwhelmingly in private hands, organized in many small private family farm units. Only 18 and 15 percent of the agricultural land in Poland and Yugoslavia, respectively, is in state and collective farms.<sup>2</sup> Their governments have actively supported private farming, providing a variety of incentives to stimulate the expansion of farm output. Such policies, for example, in Poland during recent years, consisted of (1) government increases in prices paid to farmers for their products, (2) expansion of agricultural credits to private farmers on favorable terms, (3) increasing imports of feed-stuffs and protein meal, sold to private farmers to enhance output of meat and dairy products, (4) increasing mechanization of agriculture, (5) greatly expanding the use of fertilizers by private farmers, (6) encouraging specialization and interfarm cooperation in the use of machinery, (7) stepping up government agricultural research to increase farm productivity, and (8) above all, abstaining from forced collectivization of agriculture.

Basically, two agricultural systems continue to co-exist in Eastern Europe, the one consisting of the countries with predominantly socialized agricultures—Bulgaria, Czechoslovakia, East Germany, Hungary, and Romania—and the other consisting of the countries with predominantly private agriculture, Poland and Yugoslavia. Since in all cases, agriculture functions in the context of a Communist country under a more or less centrally planned economic system (Yugoslavia, of course, has undergone significant decentralization), there is a basis for taking a comparative approach between the two types of agricultural systems in Eastern Europe: socialized versus private.

In the following pages, the recent agricultural performance of Eastern Europe will be analyzed by country and by groups of countries (socialized versus private agricultural systems). Some comparisons will also be made with the USSR, West Germany, and the United States, in an attempt better to appraise the performance of recent years.

The aim of this basically statistical study is to present the measures and assess the changes in levels of agricultural development in the East European countries since 1965. Aspects to be covered are: (1) changes in the relative importance of agriculture in the national economy of each country, (2) changes in the growth and structure of basic output and input measures, (3) trends and levels of output per capita, (4) changes in productivity of land and labor in agriculture,

<sup>2</sup> See Poland, Główny urząd statystyczny, *Rocznik statystyczny*, 1976, Warsaw, 1976, p. 236, and Yugoslavia, Savezni zavod za statistiku, *Statistički godišnjak SFRJ*, 1976, Belgrade, 1976, p. 156.

(5) progress in agricultural technology and growth of investment, (6) comparisons of output between Eastern Europe, Western Europe, the USSR, and the USA, and (8) the outlook for the next few years.

## II. PLACE OF AGRICULTURE IN THE EAST EUROPEAN ECONOMIES

Agriculture has an important position in the national economies of Eastern Europe. Until the mid-1960s, agriculture was the largest economic sector in several of the East European countries, measured in terms of its share in total employment and its share in the gross national product. Both its employment and GNP shares, however, have been declining steadily in all countries in the whole postwar period.

In 1965, Bulgaria, and Yugoslavia had still about one-half of their labor force in agriculture (table 1). Poland with more than one-third and Hungary with over one-quarter of their labor forces in agriculture, were considered predominantly agricultural countries. Czechoslovakia and East Germany, meanwhile, had each less than one-fifth of their labor force in agriculture. They were already reasonably well industrialized countries.

TABLE 1.—AGRICULTURE'S SHARE IN PERCENT OF TOTAL LABOR FORCE AND GNP

	Labor force		GNP	
	1965	1976 <sup>1</sup>	1965	1976 <sup>1</sup>
Bulgaria.....	44.9	25.8	35.2	24.0
Czechoslovakia.....	19.5	13.5	17.6	15.8
East Germany.....	14.0	10.0	15.6	12.0
Hungary.....	27.2	19.7	25.2	20.9
Poland.....	38.1	29.5	29.0	17.3
Romania.....	57.4	35.8	41.4	29.4
Yugoslavia.....	49.7	34.9	25.5	20.5
Eastern Europe.....	37.2	26.0	25.3	18.7
U.S.S.R.....	35.4	25.6	21.5	15.7
United States.....	6.9	3.5	3.5	3.0

<sup>1</sup> Preliminary.

Sources: Eastern European countries: Labor force: Agricultural employment is in terms of yearly averages of midyear data of economically active persons in agriculture taken from statistical yearbooks of the respective countries. GNP: Calculated from Thad P. Alton, present volume. The shares were adjusted for forestry. Data for 1976 were estimated from 1975 and the plan fulfillment reports for 1976 reported by the statistical offices of the respective countries. U.S.S.R.: Labor force: M. Feshbach and S. Rapawy, "Soviet Population and Manpower Trends and Policies," Joint Economic Committee, Congress of the United States. Soviet Economy in a New Perspective, 1976, p. 132. GNP: Calculated from R. Greenslade, "The Real Gross National Product of the U.S.S.R., 1950-1975," op. cit., pp. 271 and 284; for 1976 estimated from 1975 and the plan fulfillment report for 1976 reported by the Central Statistical Office in Moscow, January 1977. United States: "Statistical Abstract of the United States, 1976," U.S. Department of Commerce, 1976, pp. 356, 365 and 395, and "Survey of Current Business," 1977, No. 1, pp. 9 and S-13.

In terms of agriculture's contribution to GNP, the shares were lower than for employment because the productivity per active person in agriculture was lower than that in non-agricultural sectors. Eastern Europe as a whole and the USSR exhibited strongly agricultural characteristics when compared to the USA, which had less than seven percent of the labor force in agriculture and 3.5 percent of GNP in agriculture in 1965.

Because of rapid industrialization, the share of agricultural employment and, to a lesser degree, of agriculture's contribution to GNP has continued to fall over the last decade in all East European countries, as in the USSR. By 1976, except for Romania and Yugoslavia, in all East European countries, the share of agricultural labor had

declined to below one-third of the total. In Czechoslovakia, only 13.5 percent and in East Germany, 10 percent of total employment remains in agriculture. The share of agriculture's contribution to the total GNP decreased substantially in Bulgaria, Poland, and Romania, while in the remaining countries the decrease was small from 1965 to 1976. It is interesting to note that in 1976 the GNP share of agriculture was larger than that of employment in the total for Czechoslovakia, East Germany and Hungary. This suggests that the farmers' incomes in these countries are higher than in non-agricultural employment.<sup>2a</sup> In all countries, agriculture is still the second largest sector after industry. The trend of decline in agriculture's share in the total GNP in Eastern Europe has been similar to that in the USSR. Both Eastern Europe as a whole and the USSR have roughly one-fourth of their labor force in agriculture and generate less than one-fifth of GNP in agriculture, respectively. Compared with the USA, the relative importance of agriculture is five to six times larger in the East European and the Soviet economies.

### III. RECENT GROWTH AND STRUCTURE OF OUTPUT AND INPUTS

#### *A. Performance of Socialized Versus Private Agriculture*

The various measures of output and expenses for Eastern Europe as a whole and for two groups of countries—one with predominantly socialized agriculture, the other with overwhelmingly private agriculture—are given in tables 2 and 3 for the 1965–1976 period.<sup>3</sup> The data show the following results:

<sup>2a</sup> In Czechoslovakia for example, the average agricultural labor income was 5 percent higher than the average nonagricultural labor income in 1976. (Calculated from *Statistická ročenka 1976*, pp. 108, 122, 148–151, 340, and 342, and *Rude pravo*, January 27, 1977.)

<sup>3</sup> The measures of performance for earlier postwar years are given in G. Lazarcik, *Compendium*, 1974, pp. 328–329.

<sup>1</sup> Preliminary.

Source: See app. A.

(1) The overall performance of countries with private agriculture, which was distinctly superior to that of countries with socialized agriculture in the earlier postwar period, has continued to be superior up to the present, albeit to a more moderate degree. Between 1965 and 1976, the former groups surpassed the latter by several percentage points in crop output, and gross and net product of agriculture. The group of countries with socialized agricultures did better in animal output.

(2) Within agricultural output, both groups of countries achieved higher rates of growth in animal products than in output of crops. The countries with socialized agriculture experienced slightly higher average annual rates of growth<sup>4</sup> of animal products in the whole ten-year period than the other group. However, for 1971-75, the rate of increase was higher for the countries with private agriculture (table 2).

(3) Inputs into agriculture from other sectors continued to increase sharply due to rapid mechanization and better technology on farms. Both groups of countries about doubled current operating expenses and depreciation from 1965 to 1976. During this period, the average annual rate of growth in expenses was higher than in the earlier postwar period for the private agricultures, which have stepped up their mechanization in the last decade.

(4) Because of rapidly increasing expenses and depreciation, the gross and net products grew at much slower rates than output for both groups. Both groups of countries had higher annual rates of increase in the 1971-75 period than in the 1965-70 period. The countries with private agriculture, however, experienced higher rates of growth in their gross and net products than the countries with socialized agriculture over the 1965-76 period taken as a whole.

### *B. Performance of Individual Countries*

From 1965 to 1976, the greatest increase in agricultural output was achieved by Romania with an increase of 68 percent, followed by Yugoslavia and Hungary with 44 and 43 percent, respectively. East Germany and Bulgaria had the lowest increases in output, 23 and 24 percent, respectively, while Poland and Czechoslovakia are in the middle with 32 and 36 percent, respectively. Over the period as a whole, the output of animal products grew at a higher annual rate than output of crops in all countries except Hungary, and Poland for 1965-70. However, in the 1970-75 period the output of animal products grew much faster than in 1965-70 in all countries except Czechoslovakia. In the last seven years, all the East European countries put heavy emphasis on rapid increases in meats, eggs, and milk output in order to improve the quality of national diet.

The most spectacular rise in inputs from other sectors occurred in Romania, with a three-fold increase, followed by Hungary and Poland with more than two-fold increase, Bulgaria and East Germany with an almost two-fold increase, and Czechoslovakia and Yugoslavia with only 57 and 43 percent increases, respectively, from 1965 to 1976. Yugoslavia, although belonging to the group of countries with underdeveloped agriculture, had the lowest rise in inputs.

<sup>4</sup> All average annual rates of growth in this study are calculated as the rates given by least squares fitting of the growth equation  $I_n = I_0 (1+r)^n$  to the indexes.

Since inputs are subtracted from output to get the gross and net products of agriculture, the higher cost increases in relation to increases in output are reflected in more sluggish rates of growth in gross and net product. In fact, the net product of agriculture grew at a less than one percent average annual rate of growth in all countries except Yugoslavia and countries with private agriculture from 1965 to 1976. There was, however, a better performance in the 1970-75 period for both gross and net products in all countries. The interrelationship of total output, inputs, and gross and net product, which can be readily followed country by country in tables 2 and 3, seems to reveal a less efficient use of inputs in Bulgaria, Romania, Poland, and East Germany in the 1965-70 period. However, the incentives given to Hungarian collective farmers through a share-cropping system in the regions with specialized agriculture and favorable treatment of Yugoslav private farmers brought favorable results over the whole period.

### *C. Changes in Structure of Output and Inputs*

It may be useful to review the structural changes of Eastern European agriculture over time. Such changes are shown in table 4 in terms of percentages of output and may be summarized as follows: Since the share of animal products increased in all countries over the period, the efficiency of the transformation of intermediate produce into animal products probably increased; but increased imports of feed in recent years<sup>5</sup> also contributed to the relatively fast expanding output of animal products compared to that of crops. The share of animal products in total output in 1971-75 was from 55 to 73 percent in the more industrialized countries: Czechoslovakia, East Germany, Hungary and Poland, while in the developing countries of Southern Europe: Bulgaria, Yugoslavia, and Romania it was around one half, between 46 and 52 percent. In all countries except Yugoslavia the share of expenses and depreciation increased compared to 1966-70 shares; correspondingly the share of gross and net product declined.

1966-70.....	100	44	56	35	74	65
1971-75.....	100	40	60	44	67	56
Countries with private agriculture:						
1966-70.....	100	47	53	26	80	74
1971-75.....	100	43	57	32	74	68
Total, Eastern Europe:						
1966-70.....	100	45	55	31	76	69
1971-75.....	100	41	59	38	70	62

Sources: Output was calculated from physical quantities weighted by FAO East European and Soviet Union wheat-based price relatives for 1961-65. All other items were calculated from output and percentage distribution of these items given in national currencies (see app. A).

The East European countries with socialized agriculture are almost as dependent on inputs from other sectors as Northwestern Europe. However, these greatly increased outside resources have brought no more favorable results for socialized agriculture in Eastern Europe than they have for privately operated agriculture in Western Europe.

#### *D. Contribution of Individual Countries to the Total Output and Inputs of Eastern Europe*

The relative importance of each country as a supplier of agricultural output is shown in table 5. Bulgaria, the smallest country, supplied only about 7.8 percent of the agricultural output of Eastern Europe in 1971-75, and her importance as a supplier decreased somewhat from 1966-70 to 1971-75. In ascending order of importance came Hungary (10.6 percent), Czechoslovakia (10.8 percent), Yugoslavia, Romania, and East Germany (close to 14 percent each), and Poland, the largest supplier, accounting for 29.7 percent of the total output. The importance of Bulgaria, East Germany and Yugoslavia has declined. The share of crops increased for Hungary, Poland and Romania from 1966-70 to 1971-75. The share of animal output increased for Romania and decreased for East Germany.

TABLE 5.—PERCENTAGE CONTRIBUTION OF INDIVIDUAL COUNTRIES TO OUTPUT, EXPENSES AND DEPRECIATION, GROSS PRODUCT, AND NET PRODUCT IN AGRICULTURE

[Eastern Europe=100]

Country	Agricultural output		Crop output		Animal output		Expenses and depreciation		Gross product		Net product

East Germany.....	13.9	13.5	9.2	8.9	17.7	16.7	14.3	14.1	13.9	13.4	13.7	13.0
Hungary.....	10.1	10.6	10.3	11.4	9.9	10.0	9.9	11.5	10.0	10.0	10.1	10.0
Poland.....	29.2	29.7	28.1	29.3	30.1	30.0	29.8	31.0	28.5	28.3	28.9	28.9
Romania.....	13.5	14.0	16.1	16.3	11.3	12.4	14.1	15.6	13.7	13.8	13.2	13.0
Yugoslavia.....	14.2	13.6	17.0	16.1	11.9	11.9	6.3	4.8	16.8	17.6	17.8	19.2
Countries with socialized agriculture.....	56.6	56.7	54.9	54.6	58.0	58.1	64.0	64.2	54.7	54.1	53.3	51.9
Countries with private agriculture.....	43.4	43.3	45.1	45.4	42.0	41.9	36.0	35.8	45.3	45.9	46.7	48.1
Total, Eastern Europe.....	100.0	100.0	100.0	100.0	100.0	100.0	100.0	100.0	100.0	100.0	100.0	100.0

Sources: Output was calculated from physical quantities weighted by Eastern European and Soviet Union wheat-based price relatives for 1961-65. Expenses and depreciation, gross and net product were calculated from output and percentage distribution of these items given in national currencies (see app. A).

The share in total expenses increased for Hungary, Poland and Romania in the second period. The share of expenses for the countries with private agriculture declined somewhat from 1966-70 to 1971-75.

In terms of gross and net product, the shares in the total for Eastern Europe of Czechoslovakia and East Germany decreased from 1966-70 to 1971-75. At the same time the corresponding share of Yugoslavia increased. Other countries held their own.

#### IV. PER CAPITA TRENDS AND LEVELS OF OUTPUT

##### A. *Per Capita Output*

Trends in per capita output express better than absolute figures the quantitative improvement in the supply of agricultural products and changes in levels of self-sufficiency in domestically produced food. Tables 6 to 8 show the trends from 1965 to 1976 in agricultural output measures in relation to population for individual countries, groups of countries, and for Eastern Europe as a whole.

In general, the per capita trends are similar to the total performance measures except that the rates of change are slowed down by increases in population (table 6). Because of rapid population growth in Poland and Yugoslavia, their combined average annual rate of growth in agricultural output per capita was 2.1 percent (1.0 percent for crops, 3.0 percent for animal products) from 1965 to 1975, while for the countries with socialized agriculture the overall rate was 2.3 percent.

The behavior of output per capita for individual countries is summarized in table 6. Hungary and Czechoslovakia experienced the highest annual rates of growth of per capita output, 3.4 and 2.7 percent respectively, followed by East Germany and Poland with a 2.4 percent annual rate of growth for each, while Romania and Yugoslavia had more modest 2.2 and 1.5 percent annual rates. Bulgarian per capita annual rates were the lowest because her population grew relatively rapidly, as did that of Poland, Romania and Yugoslavia. In all countries, per capita output of animal products increased at a higher annual rate than that of crops, in line with the effort to improve protein content in national diets, particularly in the last 7-8 years.

The trend in per capita inputs exhibited an ascending pattern similar to that of total inputs in all the countries under study. Gross and net product per capita, however, was declining in the first period in most countries, but they were increasing in the second period in all countries (table 7). It should be noted that in East Germany the population has been declining since 1967, which favorably affected the per capita measures.<sup>6</sup>

##### B. *Per Capita Levels of Output*

Table 8 shows per capita comparisons of levels of output, and gross and net product in agriculture in relation to the East European level, for individual countries and groups of countries in selected periods. These findings show that the per capita level of agricultural output was lower in Czechoslovakia, Romania and Yugoslavia than the average level for Eastern Europe, while Bulgaria, Hungary and Poland were significantly above that level.

<sup>1</sup> Preliminary.

Sources: Calculated from physical quantities weighted by FAO Eastern European and Soviet Union wheat-based price relatives for 1961-65, divided by population data (see App. A).

From 1966-70 to 1971-75, however, the levels of per capita agricultural output declined in Bulgaria and Yugoslavia in relation to Eastern Europe as a whole. Hungary improved its relative position greatly, followed by Poland. Hungary has been and is the highest per capita producer of agricultural output, followed by Bulgaria and Poland, while Yugoslavia has been the lowest. Again, Bulgaria and Hungary ranked highest in per capita output of crops, while East Germany, Hungary, Poland and Czechoslovakia excelled in per capita output of animal products. The lowest per capita levels of output of crops occurred in East Germany and Czechoslovakia, while Yugoslavia and Romania rank lowest in per capita output of animal products. East Germany and Czechoslovakia have been large importers of grain in recent years. The levels of gross and net product per capita follow roughly the output pattern for individual countries. Hungary, Bulgaria, Poland and Yugoslavia rank above the average, while Czechoslovakia, East Germany and Romania are well below the average level of Eastern Europe as a whole.

The combined measures for country groups reveal that the relative levels of per capita output of animal products in the countries with socialized agriculture have increased somewhat over time, while these levels have decreased somewhat in the countries with private agriculture. The relative level of net product, however, had a tendency to increase for the countries with private agriculture on a per capita basis, in relation to Eastern Europe as a whole. The relative levels of crop output and gross and net product per capita are higher in private than in socialized agriculture.

## V. PRODUCTIVITY OF LAND AND LIVESTOCK

### A. *Agricultural Land and Land Per Farm Worker*

In most East European countries, the area of agricultural land<sup>7</sup> remained relatively stable during the period under study. In Czechoslovakia, East Germany, Hungary, Poland and Yugoslavia, agricultural land declined one to three percent, while in Bulgaria and Romania it increased one to three percent in the same period.<sup>8</sup> Poland has about 26 percent of the total agricultural land in Eastern Europe, followed by Romania and Yugoslavia with close to 20 percent each. The remaining four countries each held between 8 and 9 percent of the total agricultural land in Eastern Europe (table 16).

In comparison to the US standard, the agricultural land per person employed in agriculture is very small in all the East European countries (table 9). Because of the continuing rapid decline in agricultural employment in the last twelve years, agricultural land per employed person in agriculture rose sharply in all countries except Poland. By 1976, the number of hectares per person employed in agriculture ranged from 3.7 in Poland to 7.5 in East Germany, with 4.5 hectares the average for all Eastern Europe. The growth of agricultural land per person employed accelerated for the countries with socialized agriculture during the 1970-76 period, while for the countries with private agriculture the rate of growth decelerated in the same period. Poland actually experienced a slight decline in land per person employed in agriculture in the last seven years because agricultural employment remained stable while land declined somewhat.

<sup>7</sup> Agricultural land comprises all arable land, including orchards, gardens, vineyards, permanent and temporary meadows, pasture, and grazing land.

### B. Growth of Output and Inputs per Unit of Land

In this section we summarize our findings on output and input measures per hectare of agricultural land. As a result of the relative stability of the area in agricultural land, the output and input measures per unit of land followed the same general trends over the period under review as the total performance measures given in tables 2 and 3.

Tables 10 and 11 show the trends of various measures of production and expenses per hectare of agricultural land by country, groups of countries, and region. In general, the productivity of land increased in all countries. However, the economically less developed countries except Bulgaria had the larger annual rates of increase because their production per unit of land was low in the earlier postwar years. In all countries the average annual rate of growth of output of animal products per unit of land exceeded that of output of crops. Over the whole period, the countries with private agriculture experienced a 3.3 percent annual rate of growth of output per unit of land, while the countries with socialized agriculture had a 2.9 percent rate of growth (table 10).

Current operating expenses per unit of land increased from 1965 to 1976 most in Romania (3 times), followed by Hungary (2.3 times), Poland (2.2 times), East Germany and Bulgaria (1.8 times), Czechoslovakia (1.6 times), and Yugoslavia (less than 1.5 times). Over the whole period the annual rate of growth of expenses per unit of land was higher in the countries with private agriculture than in the countries with socialized agriculture (table 11).

From 1965 to 1976, gross and net product per unit of land increased at the highest annual rate in Yugoslavia (2.9 percent), followed by Hungary (1.0–1.7 percent), Czechoslovakia (0.9–1.5 percent), Poland (0.4–0.8 percent), East Germany, Romania and Bulgaria. The rates were higher for all countries in the 1970–75 period than in 1965–70. The countries with private agriculture had higher rates of growth in gross and net product per unit of land from 1965 to 1976 than the countries with socialized agriculture.

<sup>1</sup> Preliminary.

Sources: Data in table 3 divided by acreage of agricultural land taken from statistical yearbooks of respective countries (see app. A).

### *C. Comparison of Levels of Output and Inputs Per Unit of Land*

Relative levels of productivity of land in relation to the East European average as a base are shown in table 12. Over the postwar period the differences among countries in productivity of land have been reduced, but in 1976 they were still very large, and they were greater in the output of animal products than in that of crops. In 1976, for example, East Germany produced about three times as much animal products per hectare as either Romania or Yugoslavia. In the countries with socialized agriculture, productivity of land in terms of crop output had been about two percent higher than in countries with private agriculture in 1966-70, but this difference disappeared, and by 1976 the countries with private agriculture exceeded the socialized ones by 7 percent. Levels of animal output were higher in the socialized group.

There have been even larger differences in inputs per hectare among East European countries. Czechoslovakia's and East Germany's levels were about 6-7 times as large as Yugoslavia's in 1971-75. The use of non-agricultural inputs per unit of land in the countries with socialized agriculture exceeded by 48 percent that in the countries with private agriculture in the 1971-75 period.

Differences in levels of gross and net product per hectare among countries of Eastern Europe were smaller than those of inputs. The net product per hectare of land in the countries with private agriculture exceeded that in the countries with socialized agriculture by 5 percent in the 1966-70 period, and by 13 percent in 1976. The level of Romanian gross and net product per unit of land remained the lowest among the East European countries.

### *D. Yields of Selected Crops per Hectare*

Table 13 provides a more specific view of comparative levels and trends in productivity of land among various East European countries. It shows yields per hectare for selected crops: wheat, rye, potatoes, and sugar beets. In the 1950's the yields in all the East European countries, except East Germany and Czechoslovakia, were substantially below those in West Germany. In Bulgaria, Romania and Yugoslavia the average yields were one half or less than half of those of West Germany. It should be noted that the natural fertility of West German land is not better than that of Eastern Europe; much of the land in the Danubian Plains is of superior quality. In the last 17 years an effort has been made to improve the productivity of land, and in most of the East European countries yields have increased substantially. In all the countries, the yields of wheat improved the most, and by 1974-76, the differences in yields between East European countries and West Germany became much smaller. The rates of improvement in rye, potatoes, and sugar beets were less uniform among the East European countries; Czechoslovakia, Hungary, Poland and Yugoslavia showed most rapid progress in yields of wheat, rye, potatoes and sugar beets, but their yields are still quite low compared to West German yields in 1974-76.

### *E. Yields Per Livestock Unit*

Throughout the postwar period, the yields of meat per pig were increasing steadily from low levels. In the decade from 1965-67 to 1974-76 these yields increased in all countries by between 8 and 20 percent (table 14).

<sup>1</sup> Data for 1976 are preliminary.

Sources: Calculated from FAO yearbooks and statistical yearbooks of respective countries.

In the 1950's milk yields per cow were very low in Bulgaria, Romania and Yugoslavia, but they have since increased substantially, especially in Bulgaria and Romania. The countries with higher milk yields, i.e., Czechoslovakia, East Germany, Hungary and Poland also achieved good increases from 1965-67 to 1974-76.

Yields of eggs per hen increased by between 23 to 53 percent in Bulgaria, Hungary, Poland, East Germany, Czechoslovakia, Yugoslavia and Romania, in ascending order, from 1965-67 to 1974-76. As of 1974-76, the yields per livestock unit remained lower in all East European countries than in West Germany. The differences in yields, however, have been reduced greatly among countries in recent years.

## VI. PRODUCTIVITY OF LABOR IN AGRICULTURE

### *A. Decline in Agricultural Labor Force*

Labor data used in this study are mostly in terms of the full-time employment equivalents in agriculture, which includes farmers, their wives working in agriculture, helping family members, and hired labor. The quality of agricultural labor statistics varies from country to country. East German, Czechoslovak, Hungarian and Polish labor data are homogeneous, while those for the other East European countries are less standardized, and consequently the quality of labor units is less homogeneous.

In all of the East European countries the labor force in agriculture continued to decline substantially from 1965 to 1976. The percentage declines for different countries are given in table 15.

TABLE 15.—EMPLOYMENT IN AGRICULTURE

<sup>1</sup> Preliminary.

Source: See app. A.

Bulgaria and Romania had the largest exodus of labor from agriculture (about one-third), followed by East Germany (one-fourth decline); Czechoslovakia, Hungary and Yugoslavia (one-fifth, each), while Poland experienced very stable employment from 1965 to 1976. In the last six years the largest decreases occurred in Romania, Bulgaria, Czechoslovakia and Hungary.

Table 16 shows the percentage distribution of agricultural labor. The Polish agricultural labor force in 1976 accounted for 32 percent, the Romanian for 23 percent, and the Yugoslav for 21 percent of the total East European agricultural labor force. The remaining four countries together account for only 24 percent of the total.

### *B. Growth of Output and Inputs Per Worker*

As a result of the decline in the agricultural labor force, a consequence of continuing industrialization, the productivity of labor in agriculture increased sharply over the postwar period. Tables 17 to 19 summarize the trends in labor productivity by country, groups of countries, and region from 1965 to 1976.

Obviously, countries with the largest declines in labor experienced the largest increases in labor productivity, provided that total output was not lagging. Romania, Bulgaria, Hungary, Yugoslavia and Czechoslovakia had the largest increases in output per unit of labor during this period; they were followed by East Germany and Poland. From 1965 to 1975, the average annual compound rate of increase was higher for the countries with socialized agriculture (6.2 percent) than for those with private agriculture (3.9 percent); the agricultural labor force declined at a faster rate in the former group than in the latter. In Eastern Europe as a whole agricultural output per unit of labor increased by 5.1 percent annually in this period. During 1970-75, the growth of output per unit of labor was higher for all countries than in the 1965-70 period.

The increases in inputs per worker in agriculture were very impressive in all countries. The most dramatic increase occurred in Romania, with about a 4.6-fold rise over the 1965-76 period. In descending order, other increases were Bulgaria and Hungary (2.8-fold rise), East Germany (2.4-fold rise), Poland (2.2-fold rise), Czechoslovakia (2-fold), and last, Yugoslavia (1.8-fold rise). Again, the countries with socialized agriculture had larger increases in inputs per unit of labor (a 10.6 percent annual rate of growth) than the countries with private agriculture (8.7 percent annual rate of growth), from 1965 to 1975.

The increases in gross and net product per unit of labor in descending order were largest in Yugoslavia, Romania, Bulgaria, Czechoslovakia and Hungary, and lowest in East Germany, and Poland (table 18). In the 1965-75 period the countries with socialized agriculture achieved higher rates of growth in gross and net product per unit of labor (4.3 and 3.5 percent, respectively) than the countries with private agriculture (2.3 and 2.1 percent).

On the whole the East European performance per unit of labor has been impressive. It reflects largely the absorption of the extensive disguised agricultural unemployment that existed in this area, by transfers of labor to non-agricultural sectors of the economy, permitting better overall use of available human resources.

### *C. Levels of Output and Inputs Per Worker*

It may be useful to bring into focus comparative levels of productivity of labor among the different countries in relation to the East European average level. Such data are shown in table 19.

<sup>1</sup> Preliminary.

wheat-based price relatives for 1961-65 divided by the number of employed people in agriculture taken from statistical yearbooks of respective countries (see app. A).

Sources: Calculated from physical quantities weighted by FAO East European and Soviet Union

Very large differences in productivity of labor continue to exist among the individual countries. Before the war a Bulgarian, Romanian or Yugoslav worker in agriculture produced hardly one-sixth as much output as an East German worker. As of 1976, the Romanian and Yugoslav worker still produced only about one-fourth of the East German output per worker. Czechoslovakia has been the second highest in output per worker, followed by Hungary, Bulgaria, Poland, Romania, and Yugoslavia on a rapidly descending scale.

The difference in relative levels of output of animal products per worker have been even greater. Relative levels of inputs and gross and net product per worker were approximately of the same order of magnitude as in the case of output.

In comparing the groups, we find that in the 1966-70 period the output, gross product, and net product per worker in countries with socialized agriculture were approximately 4 to 19 percent higher than those in countries with private agriculture. By 1971-75, however, the level of output, gross product, and net product per worker in the former group exceeded that of the latter by between 11 and 34 percent. The worker in the countries with private agriculture had about one-half the magnitude of the inputs at the disposal of the worker in the countries with socialized agriculture in 1976.

## VII. PROGRESS IN AGRICULTURAL TECHNOLOGY

### A. Progress in Mechanization

A close relationship between mechanical power input and productivity of land and labor has been observed in many countries.<sup>9</sup>

A widely used indicator of the extent of mechanization is the number of tractors per unit of land and per unit of labor. Table 20 presents estimates of tractors in terms of standard 15 H.P. tractor units per 1,000 hectares of agricultural land and per 1,000 workers in agriculture by country, groups of countries, and major regions. Our findings show that in the 1963-67 period the extent of the use of mechanical power was still low, by West European standards, in most of the East European countries. Only Czechoslovakia and East Germany were close to West European levels. However, the level of West European mechanization was, in turn, low in comparison to that of the United States, where there were 2,250 tractors per 1,000 full-time workers in agriculture in 1975.<sup>10</sup>

<sup>1</sup> Data for 1976 are preliminary.

Sources: Calculated from statistical yearbooks of respective countries and FAO yearbooks and monthly statistical bulletins.

Progress in mechanization has continued to gain momentum. In all the countries the rates of increase were spectacular; in fact the percentage increases exceeded those of Western Europe. As a result, the differences among individual countries and between Eastern and Western Europe have somewhat narrowed with the passage of time. By the 1973-76 period, Czechoslovakia and East Germany had about four times as many tractors per unit of land and seven to eight times as many tractors per worker as Romania. Yugoslavia's level of mechanization was somewhat higher than that of Romania, and Poland's intensity in the use of tractors was about a third to a half of that of either Czechoslovakia or East Germany. Polish and Yugoslav progress in mechanization gained the fastest upward momentum in the last 12 years. The differences in relative levels of mechanization between the countries with socialized and private agriculture, taken as groups, narrowed dramatically from the 1963-67 to 1973-76 period. The pace of mechanization was much faster in the countries with private agriculture.

Western Europe has nonetheless retained its lead in mechanization over Eastern Europe. In the 1973-76 period, it still had about two times as many tractors per unit of land and about four times as many tractors per worker as Eastern Europe. Although progress in the mechanization of agriculture in Eastern Europe has been at a faster

rate than in Western Europe in the last 15 years, there is still plenty of room for further improvement toward the West European level.

### B. Growth of Fertilizer Consumption

Most of the East European countries did not turn seriously toward increased use of fertilizers until the late 1950's, but since then they have made tremendous progress. Table 21 shows that by 1963-68, consumption of fertilizers per unit of land was getting closer to the West European level in most East European countries. Czechoslovakia and East Germany already had extremely high levels of fertilizer use; in fact they exceeded the West European level by 1.5 to over 2.0 times and that of Eastern Europe by about three times in the 1963-68 period. Bulgarian, Polish and Hungarian consumption per hectare were getting close to the level of Western Europe, and they were at about the average for Eastern Europe in the same period.

TABLE 21.—CONSUMPTION OF COMMERCIAL FERTILIZERS PER HECTARE OF AGRICULTURAL LAND

<sup>1</sup> Data for 1976 are preliminary.

Sources: Calculated from statistical yearbooks of respective countries and FAO yearbooks and monthly statistical bulletins.

The consumption of fertilizers between 1963-68 and 1973-76 has been expanding at the fastest rate in Hungary, Poland and Romania, increasing about three times, followed by Czechoslovakia, Yugoslavia, East Germany and Bulgaria in descending order.

East Germany, Czechoslovakia, Hungary and Poland were the highest users of fertilizers per hectare of agricultural land in Eastern Europe. Their respective annual consumption was 287, 214, 204 and 175 kilograms per hectare in the 1973-76 period. Bulgaria, one of the lowest users of fertilizers in the 1950's, also became a high user with an annual consumption of 105 kilograms in the 1973-76 period. Czechoslovakia, East Germany and Hungary exceeded the West European consumption level by 22, 63 and 16 percent, respectively, in the 1973-76 period. Poland achieved an average level of 175 kilograms per hectare, or the same as in Western Europe, while Romania and Yugoslavia remained the lowest users with 69 and 48 kilograms per hectare annually in the same period.

The countries with socialized agriculture had fertilizer consumption per unit of land 59 percent higher than the countries with private agriculture in the 1963-68 period. That margin, however, was reduced to about 28 percent by 1973-76.

Eastern Europe as a whole compares quite favorably in fertilizer consumption with Western Europe. In relation to the United States, however, where the consumption of fertilizer was 968 kilograms per hectare in 1975,<sup>11</sup> there is plenty of room for increase in consumption toward equality. Nevertheless, this heavily increased application of fertilizers already has paid off with significantly increased yields in Eastern Europe.

### *C. Scientific Methods on the Farm*

The adoption of high-yielding crop varieties and livestock breeds helped to increase yields per unit of input in all the East European countries. Research on improvement of seeds has been stepped up by the agricultural research institutes, partly under the coordination of the Council for Economic Mutual Aid's Permanent Commission on Agriculture. A significant increase in wheat yields has been attributed to the introduction of improved Soviet hard wheat varieties (Mironovskaya-808, Bezostaya-I, Kavkaz and Aurora) during 1966-76. These wheat strains were sown on more than 70 percent of the wheat area in Czechoslovakia, East Germany and Hungary, and on more than 85 percent in Bulgaria in recent years. Also, hybrid varieties of corn and better strains of barley, rye and oats were introduced. The development of improved breeds of livestock has contributed to increased yields of milk per cow, eggs per hen, higher dressing rates of livestock, leaner types of animals, and higher daily gains in liveweight for all livestock. New breeds of livestock are being imported from Western Europe and the USA, especially by Hungary and Yugoslavia.

Irrigation and drainage of agricultural land on a large scale is increasing the productivity of land in all East European countries. Technological knowledge has been disseminated through rapidly increasing numbers of agricultural technical institutes and agricultural colleges. The number of trained agronomists has increased several times in every East European country. Application of more advanced farming methods undoubtedly has contributed to the higher productivity of land and labor in Eastern Europe.

The recent development of agro-industrial complexes is increasing the overall efficiency of agriculture through local processing of agricultural products, employing seasonally idle agricultural labor, and diffusing technical knowledge in rural areas of Eastern Europe.<sup>12</sup>

### *D. Investment in Agriculture*

The recent growth of gross fixed agricultural investment and its share in total investment in Eastern Europe is shown in table 22. These investment series should be interpreted with care, assuming a considerable margin of error, because for some of these countries not enough is known about the prices of investment goods, and the terms of measurement vary from country to country. Yet, despite their shortcomings, these series may give us a general picture of trends in investment in the recent years.

<sup>11</sup> See U.N. FAO, "Production Yearbook, 1975," pp. 24 and 287.

<sup>12</sup> See *Zemelska ekonomika*, 1976, No. 6, pp. 405-414.

Throughout Eastern Europe there has been a substantial increase in agricultural investment, generally with the less developed countries showing the greater increases: Romania, Yugoslavia, Poland, Hungary and Bulgaria experienced high increases in investment in both periods (1966-70 and 1971-75), shown in table 22. In comparison to West Germany, all of the East European countries seemed to have a much higher rate of investment in recent years. However, West Germany, despite her low increase in investment, improved her performance in agriculture substantially (tables 13 and 14).

TABLE 22.—GROSS FIXED AGRICULTURAL INVESTMENT AND ITS SHARE IN THE TOTAL INVESTMENT

Sources: Calculated from statistical yearbooks of respective countries (see app. A).

Agricultural investment may be usefully related to total investment and then compared with agriculture's share in total GNP. These relationships are shown in table 22 and table 1. We notice that agriculture's share in total investment was relatively low, from 9 to 16 percent, depending on country, in the 1966-70 period. On the other hand, the contribution of agriculture to the total GNP was over two times as large as the investment share in Romania, Bulgaria and Yugoslavia, almost two times as large in Poland, about 59 percent larger in Hungary and Czechoslovakia, and 11 percent larger in East Germany in the 1966-70 period.

In the subsequent 1971-75 period, agriculture's share in total investment had a general tendency to decrease from a fraction of one percent in Bulgaria and Czechoslovakia to a maximum decrease of 2.9 percent in Hungary. However, the difference between agriculture's share in total investment and its share in GNP has shrunk. In East Germany, agriculture's share in total investment exceeded its share in GNP. In the still predominantly agricultural countries, Yugoslavia and Romania, the ratio of agriculture's investment share to its GNP share is below one-half. This would seem to suggest that agriculture is partly financing industrialization in these countries. In the final analysis, this ratio reflects governmental price and taxing policies towards agriculture.

It is to be noted that the Soviet Union allocated 26.2 percent of total investment to agriculture in the 1971-75 period.<sup>13</sup> This is a higher

<sup>13</sup> See David W. Carey, "Soviet Agriculture: Recent Performance and Future Plans," In U.S. Congress Joint Economic Committee, "Soviet Economy in a New Perspective," p. 590.

percentage than in any other East European country for the same period.

### VIII. SIZE COMPARISONS OF OUTPUT BETWEEN EASTERN EUROPE, USSR, WESTERN EUROPE, AND USA

In this section we summarize our finding of size comparisons of agricultural output between Eastern Europe, the USSR, Western Europe, the USA, and individual countries for selected periods in terms of international wheat units (table 23).

TABLE 23.—COMPARISONS OF LEVELS OF AGRICULTURAL OUTPUT AND AGRICULTURAL OUTPUT PER CAPITA: EAST EUROPEAN COUNTRIES, U.S.S.R., WESTERN EUROPE, AND UNITED STATES

<sup>1</sup> Preliminary.

Sources: Calculated from physical quantities weighted by FAO Eastern European and Soviet Union wheat-based price relatives for the 1961-65 period for Eastern Europe and the Soviet Union; for Western Europe, the Western European FAO wheat-based price relatives for the 1961-65 period were used as weights; and for the United States, the North American FAO wheat-based price relatives for the 1961-65 period were used as weights. Physical quantities and population data were taken from statistical yearbooks of the respective countries (see bibliography and app. A). The FAO wheat-based price relatives for the 1961-65 period were taken from: United Nations, Food and Agriculture Organization, "Production Yearbook, 1975" Rome, 1976, pp. 470-471.

From 1966-70 to 1971-75 the relative magnitude of output of most East European countries and of Eastern Europe as a whole in comparison to the USA increased somewhat, because the agricultural output in those countries increased at a slightly higher rate than in the USA. The USSR and West European magnitudes, however, declined slightly. In 1976, the magnitudes of all countries decreased in comparison with the USA. East European agricultural output declined from 42 percent of the US output in 1971-75 to 39 percent in 1976, that of the USSR from 74 to 65 percent, and that of Western Europe from 86 to 77 percent of the USA because the USA had an above-average and the other countries a below-average 1976 harvest year. Other authors show similar relative sizes of the US and USSR outputs (USSR as percent of USA 77 in 1966-70 and 75 in 1971 when both are valued in 1968 ruble prices).<sup>14</sup>

International comparisons of output per capita provide better measures of relative self-sufficiency than comparisons of total agricultural output. In most years, the agricultural output of the USSR

<sup>14</sup> See F. Douglas Whitehouse and Joseph F. Havelka, "Comparison of Farm Output in the U.S. and USSR, 1950-1971," U.S. Congress, Joint Economic Committee, "Soviet Economic Prospects for the Seventies, A Compendium of Papers," U.S. Government Printing Office, 1973, p. 358. The authors also give a comparison in constant 1957-59 dollars, which yields a higher magnitude for the USSR than the comparison in rubles.

and that of Eastern Europe is not fully sufficient in providing an adequate food supply to that region's population, while the United States' agricultural output is more than adequate in providing a high level of nutrition to its population. Hence comparing the per capita levels of agricultural output in terms of the US per capita output will provide a rough measure of the degree of "self-sufficiency" if we assume that the US level of per capita output is about 20 percent above the norm of an adequate food supply.<sup>15</sup> The per capita levels of agricultural output in different countries in terms of the USA equals 100 for 1966-70, 1971-75 and 1976 are given in table 23.

These per capita levels indicate that the USSR produced roughly 63 percent of the output of the United States in the 1966-1975 period and only 54 percent in 1976, which is clearly inadequate if we consider 80 percent of the US level to be the norm for an industrial society.

Eastern Europe as a whole shows a more favorable per capita level of output than the Soviet Union. In the 1971-75 period it produced roughly 70 percent as much agricultural output per capita as the United States. This level represented an increase of 3 percentage points from 67 percent in the previous 1966-70 period. In 1976 the level dropped, however, to a little over 65 percent of the USA's because of poor harvests in Eastern Europe and an above-average harvest in the United States. The per capita levels of output in Eastern Europe in comparison to the United States, and even more so vis-a-vis the Soviet Union, were improving in the 1971-75 period as compared to the previous 1966-70 period. Both groups, socialized and private agriculture, seem to be on a par in per capita levels of output during the period under study.

As for the individual countries, the highest per capita level in the 1971-75 period was achieved in Hungary, with 89 percent of the US level, followed by Bulgaria, with 80 percent, Poland with 78 percent, East Germany with 70 percent, Czechoslovakia with 65 percent, and at the bottom, Romania and Yugoslavia with 59 and 57 percent, respectively. If we refer to the norm given above (80 percent of US output per capita equals self-sufficiency), only Hungary would seem to have about 10 to 12 percent of her output available for export while providing adequate food for the domestic population. Bulgaria and Poland seem to be just about self-sufficient, while East Germany, Czechoslovakia, Romania and Yugoslavia would be considered to have 13 to 28 percent deficits in domestic output if they were to maintain roughly the US food consumption level.

Western Europe seems to be the most deficient region in per capita food supply, producing only a little over one-half as much as the USA. About one-third of Western Europe's food requirements would have to be imported if the US consumption level were the norm.

The above comparisons of levels are affected by the composition of output and prices in various countries, which in turn reflect differences in natural resources, levels of income, tastes and governmental agricultural policies. Although they are very crude indicators of relative sizes of levels of per capita output between selected countries and regions, they seem to show clearly that the domestic output of food in Eastern Europe as a whole, and even more so in the Soviet

<sup>15</sup> For the 1971-75 period, in the USA 92 percent of agricultural output was consumed domestically after subtracting net agricultural exports from total output (see U.S. Department of Agriculture, "Agricultural Statistics, 1975," pp. 481, 576, and "Survey of Current Business," 1976, No. 12, p. 36). However, it is believed that U.S. consumption levels are more than adequate, and we reduce it to 80 percent as a fair norm for illustrative purposes.

Union, was deficient by some 12 to 22 percent in the 1971-75 period if the US norm were to be maintained. In 1976 this deficiency was even larger because of poor harvests in most East European countries.

## IX. CONCLUSION AND OUTLOOK

Some tentative conclusions on the recent performance of East European agriculture may be summarized as follows:

(1) Agricultural performance as reflected in our measures has been uneven among the East European countries and over the period under study. Agricultural output in the 1965-70 period experienced a slow rate of growth of about 2 percent per year on the average in Eastern Europe as a whole, and for both the socialized and private groups of agriculture. In the 1971-75 period, output grew at an average rate of 4.1 percent for the whole region, or about double the rate for the previous five years in both groups of countries. In Hungary and Romania output has expanded most rapidly of all the countries, followed by Yugoslavia, Czechoslovakia and Poland. In Bulgaria and East Germany, output grew sluggishly between 1965 and 1976 (see table 2).

(2) Poland and Yugoslavia, as a group with predominantly private agriculture, had a growth performance in most production measures equal to or better than that of the group of countries with socialized agriculture. Some advantage of private agriculture over socialized agriculture seems to have continued up to the present (see tables 2 and 3).

(3) In terms of gross and net product (i.e., agriculture's contribution to GNP and NNP), the group of countries with private agriculture surpassed the group of countries with socialized agriculture by a comfortable margin.

Between 1965 and 1976 the former group, with small-scale, private farming, enjoyed increases of 18 and 14.8 percent in gross and net product, respectively, while the latter group, with large-scale, mechanized socialized farming, attained 15.6 and 7.6 percent increases of gross and net product, respectively (see table 3).

(4) Since the countries with socialized agriculture had allocated large quantities of non-agricultural inputs to agricultural production but had smaller increases in gross product and net product than those with private agriculture, they probably have used their productive resources less efficiently than the group with private agriculture.

(5) The better performance of the countries with private agriculture over the countries with socialized agriculture is evident in several growth measures. The countries with private agriculture exceeded or lagged behind (-) the performance measures of the countries with socialized agriculture between 1965 and 1974-76 as follows:

In:	By margin of (percent)
Crop output.....	4.5
Animal output.....	-4.5
Gross product.....	2.3
Net product.....	6.5
Crop output per capita.....	1.2
Animal output per capita.....	-7.5
Net product per capita.....	3.1
Agricultural output per unit of land.....	0.9
Gross product per unit of land.....	4.5
Net product per unit of land.....	8.7

(6) Progress in mechanization of agriculture has been very impressive in Eastern Europe, but its level, except in Czechoslovakia and East Germany, is still behind that of Western Europe. Yugoslavia and Romania have the lowest levels of mechanization. However, the application of commercial fertilizers is in general close to the West European level, and in Czechoslovakia, East Germany and Hungary the use of fertilizers per hectare of land is higher than in Western Europe as a whole. Hungary, Poland and Romania saw the greatest expansion in the use of fertilizers in the period under review.

(7) The introduction of higher-yielding varieties of wheat, corn, barley, rye and oats along with the increased use of fertilizers brought rapidly increasing yields per unit of land in all the East European countries. Livestock yields are being increased by importing high-producing breeding stock from the USA and Western Europe, especially by Hungary.

(8) Considerably greater emphasis has been placed on animal output in recent years in order better to satisfy rapidly increasing demands for products of animal origin in all the East European countries. Yields per unit of livestock have increased significantly in the last 10 years.

(9) All the East European governments are putting increasingly stronger emphasis on increasing agricultural output and the productivity of land and labor. To effect this, they are channelling more resources into agriculture in the form of increased investment in machinery and equipment, land irrigation, better technology on farms, technical education, more flexibility and incentives to managers of farms, and pricing systems more responsive to changing scarcities, especially as shown in sharply increased prices paid to farmers, and increased fringe benefits.

(10) An international comparison of agricultural outputs shows that Eastern Europe as a whole accounted for about 61 percent as much output as the USSR and about 39 percent as much as the USA in 1976. In turn, the USA's output was about 55 percent larger than that of the USSR in 1976. In terms of per capita levels of agricultural output, the USA ranks the highest, followed by Hungary, Bulgaria, Poland, East Germany, Romania, Czechoslovakia, Yugoslavia and the USSR, in descending order for 1976.

(11) On the basis of the above overall growth performance measures, one is led to a conclusion that thus far socialized agriculture in the countries of Eastern Europe has not lived up to the expectations of their communist governments for higher growth rates in production and in productivity than private family farming could achieve. Our comparisons of socialized versus private farming in Eastern Europe do not show better overall results for the former.

(12) The findings of this study afford a critique of agricultural systems in Europe. With the evident trend toward rational use of resources in Eastern Europe, readers there, as elsewhere, may want to ponder the significance of the systems as influences on productivity. Their concern with agricultural efficiency has prompted them to decentralize to some degree, to try to rediscover the springs of motivation through higher producer prices, higher profit, and other personal incentives. Scarce foreign exchange has been allocated to importing advanced agricultural technology. Agriculture remains a critical sector in Eastern Europe in view of the rising populations

and the sharply increasing demand for more and higher quality, protein-rich foods of animal origin.

After a relatively poor agricultural year for most of the East European countries in 1976, the outlook for the remaining part of this decade appears favorable, particularly for 1977. Mild temperatures and above normal precipitation during the past two months have brought soil moisture to normal levels throughout the region except parts of East Germany and Bulgaria, which have moisture deficit owing to last year's severe drought.<sup>16</sup> Barring adverse weather developments in the next few months, there should be a sharp rebound in agricultural production from last year's depressed levels (experienced in all countries except Romania and Yugoslavia).

The official gross agricultural production plans for 1977 are quite optimistic, but the five-year plans for 1976-80 are perhaps more realistic. Table 24 summarizes the officially reported gross production results for the past two five-year plan periods and the average growth rate targets for the 1976-80 five-year plans.

<sup>5</sup> Represents the decline in net material product of agriculture (national income of agriculture).

Sources: National plans and plan fulfillment reports of respective countries published in statistical bulletins of these countries; and "Supplement to World Economic Survey, 1975, Fluctuations and Development in the World Economy, Chapter II, Problems and Policies in the Centrally Planned Economies," United Nations, New York, 1976, p. 65.

Czechoslovakia and Hungary overfulfilled their 1971-75 production plans, but all the other countries including the Soviet Union failed to reach their planned targets. Eastern Europe as a whole reported a 3.1 percent average annual rate of growth in gross agricultural production which fell short of the 3.5-4.0 percent planned.

For 1976-80, the planned growth rates for gross agricultural production were set at about the same levels as for 1971-75. Bulgaria and Hungary set slightly higher goals, and Poland and Romania somewhat lower. The planned 1976-80 average annual rate of growth for Eastern Europe as a whole is 0.2 percent lower than that planned for 1971-75, but about 0.4 percent higher than the 3.1 percent realized in that period.

What are the prospects for the 3.3-3.8 percent planned 1976-80 average annual rate of growth of gross agricultural production in

<sup>16</sup> See U.S. Department of Agriculture, "News", March 18, 1977, p. 6.

Eastern Europe? Because of adverse weather, all countries except Romania have fallen far behind the target rate for 1976 by several percentage points. The plan called for a 5.8 percent average increase but the reported actual increase was only 1.1 percent. The targets for 1977 are set roughly at the same level as for 1976 for Eastern Europe as a whole. This suggests that the planners are still hoping to meet their 1976-80 goals.

Success in this endeavor will depend on two major factors: weather and continuation of increased supply of resources to agriculture. The weather cannot be planned, but even if we assume that it will prove more favorable than the average past experience, increased inputs into agriculture will be required to fulfill the production plans.

Since emphasis in the current plans is on increases in livestock production to meet increasing domestic demand for meat and dairy products, Eastern Europe confronts an insufficient domestic feed base that has to be supplemented by sharply increased imports of feed grains, oilcake meal, soybeans and other protein concentrates in order to fulfill production plans.<sup>17</sup> Eastern Europe in recent years has become increasingly dependent upon regular imports of feedstuffs. The net imports of feed grains rose from 2.1 million metric tons in 1970-71 to 7.2 million tons in 1976-77,<sup>18</sup> and imports of oilseed cake, soybeans and soybean meal increased from 3.4 million tons to 6.3 million tons in the same period.<sup>19</sup> Such imports must be increased if the livestock production plans are to be met. Since most of the suppliers of these feeds are hard currency countries (USA, Canada, Australia, and South America), Eastern Europe will face difficult choices in allocating their limited hard currency flows to finance increasing feed imports. The East European countries have steadily and increasingly relied upon imports of feed grain, oil cake, soybeans, soybean meal, feed concentrates, vitamin supplements, and breeding stock from North America, Australia, Latin America, and other countries. Given East European expectations for an increased supply of meat, this trend is expected to continue. Finally, an important requirement for improved performance of agriculture is the continuing provision of a variety of production incentives to farmers but on a larger scale than in the past.

## APPENDIX A. NOTES AND SOURCES TO TABLES 1 TO 24

1965-76

All quantity series and national prices needed for the construction of tables 1 to 24 were taken from publications published by the Research Project on National Income in East Central Europe, Columbia University, Riverside Research Institute (RRI), and L.W. International Financial Research (LWIFR), as follows:

Bulgaria.—Gregor Lazarcik and Wassyl Znayenko, "Bulgarian Agricultural Production, Output, Expenses, Gross and Net Product, and Productivity, 1939 and 1948-1967," OP-32, R.R.I, 1970.

Gregor Lazarcik, "Bulgarian Agricultural Production, Output, Expenses, Gross and Net Product, and Productivity at 1968 Prices, 1939, and 1948-1970," OP-39, 1973 (updated to 1976). R.R.I and L.W.I.F.R., New York.

Czechoslovakia.—Gregor Lazarcik, "Production and Productivity in Czechoslovak Agriculture, 1934-38 and 1946-1967." Ph.D. dissertation (updated to 1976). Columbia University.

Gregor Lazarcik, "Comparison of Czechoslovak Agricultural and Non-agricultural Incomes in Current and Real Terms, 1937 and 1948-1965." OP-20, 1968. Columbia University.

East Germany.—Gregor Lazarcik, "East German Agricultural Production, Expenses, Gross and Net Product, and Productivity, 1934-38 and 1950-1970." OP-36, 1972 (updated to 1976). R.R.I, New York.

Hungary.—Laszlo Czirjak, "Hungarian Agricultural Production and Value Added, 1934-38 and 1946-1965," OP-14, 1967 (updated to 1976). Columbia University.

Laszlo Czirjak and Paul Marer, "Comparison of Agricultural and Non-agricultural Incomes in Current and Real Terms, 1938 and 1949-70." OP-21, 1973. R.R.I and L.W.I.F.R., New York.

Poland.—Andrzej Korbonski and Gregor Lazarcik, "Polish Agricultural Production, Output, Expenses, Gross and Net Product, and Productivity, 1934-38, 1937 and 1946-1970," OP-37, 1972 (updated to 1976). R.R.I, New York.

Romania.—Gregor Lazarcik and George Pall, "Romania: Agricultural Production, Output, Expenses, Gross and New Product, and Productivity, 1938 and 1948-1971," OP-38, 1973 (updated to 1976). R.R.I and L.W.I.F.R., New York.

Yugoslavia.—Joseph Bombelles, "Yugoslav Agricultural Production and Productivity, Prewar and 1948-1967," OP-31, 1970 (updated to 1976). R.R.I, New York.

Countries of Eastern Europe.—Thad P. Alton, Elizabeth M. Bass, Gregor Lazarcik, and Wassyl Znayenko. "Agricultural Output, Expenses, Gross Product, Depreciation, and Net Product in Eastern Europe, Prewar and 1950-1975," OP-49, 1976 (updated to 1976). L.W.I.F.R., New York.

U.S.A. and U.S.S.R.—United Nations, Food and Agriculture Organization. "Production Yearbook, 1975." Rome, 1976.

#### NOTE FOR 1976

Our indexes for 1975 (weighted by wheat-based price relatives for 1961-65) were extended to 1976 by means of crop output indexes, animal products output indexes and agricultural production indexes for individual countries calculated from plan fulfillment reports of respective countries for 1976 published in January and February 1977 issues for Bulgaria: "Rabotnichesko delo," Sofia, daily; for Czechoslovakia: "Rude pravo," Prague, daily, and "Hospodarske noviny," Prague, weekly; for East Germany: "Neues Deutschland," Berlin, daily, and "Die Wirtschaft," Berlin, weekly; for Hungary: "Nepszabadsag," Budapest, daily, and "Magyar Nemzet," Budapest, daily; for Poland: "Trybuna ludu," Warsaw, daily, and "Zycie gospodarcze," Warsaw, weekly; for Romania: "Elоре," Bucharest, daily, and "Scinteia," Bucharest, daily; for Yugoslavia: "Borba," Belgrade, daily; for U.S.A.; "Survey of Current Business," 1977, Nos. 1-2; for U.S.S.R.: "Pravda," Moscow, daily.

#### APPENDIX B. METHODOLOGICAL NOTES

The definition of agriculture as an economic sector and the concepts and definitions of output and input measures used in this study have been set forth in detail in an earlier study of East European agriculture presented to the Joint Economic Committee of the U.S. Congress in 1970. (See Gregor Lazarcik, Compendium 1970, pp. 467-472.) Perhaps only a very brief summary of the methodology used here may be in order for the benefit of the reader.

Forestry, fishing and hunting are not included in agriculture, as may be the case in some U.N. statistics. The coverage of our data ranges from 95 percent to almost 100 percent of agricultural output, depending on the country. Our measures of output and inputs are based on physical quantity series consisting of from 70 to over 100 individual products for each country. Since the official output and input

measures sometimes differ from those used by international organizations, or are not published, an independent, uniform calculation of all important measures was made by the Research Project on National Income in East Central Europe in New York in accordance with standard international definitions. These measures are presented in this study.

*Pricing system.*—The best available uniform price weights to facilitate international comparisons of East European countries are the newly calculated wheat-based price relatives for Eastern Europe and the USSR for 1961–65 devised by the Food and Agriculture Organization of the United Nations for the calculation of regional and world agricultural production. These Eastern European price-weights were used in this study for the aggregation of agricultural output. These price relatives for agricultural products are the arithmetic averages of all the national wheat-based price relatives weighted by the respective country's production of the farm products concerned. The national wheat-based price relative consists of the national producer price of the product expressed as a percentage of the national producer price of an equal weight of wheat. For most products the prices are weighted averages of producer prices for the 1961–65 period. (See U.N. Food and Agriculture Organization, *Production Yearbook 1975*, vol. 29, Rome, 1976, pp. 469–471).

Other measures (i.e., operating expenses, gross product, depreciation, and net product of agriculture) were derived from output (calculated in wheat-based price relatives for 1961–65) on the basis of percentage relationships of these measures for each country and each year calculated in each country's constant prices paid to or by producers for their products or production inputs. (The national price weights used were as follows: Bulgaria, 1968 leva; Czechoslovakia, 1970 crowns; East Germany, 1965 marks; Hungary, 1970 forints; Poland, 1970 zlotys; Romania, 1970 lei; and Yugoslavia, 1964 dinars.) This system of valuation takes into account the differences in relative scarcities in each country, and at the same time it permits international comparisons in terms of uniform wheat-based price relatives for all countries.

The index numbers of various output and input measures are computed by a modified Laspeyre's formula (the formula is  $\frac{\sum P_k Q_i}{\sum P_k Q_k}$ , where  $P_k$  represents the selected constant prices,  $Q_k$  the quantities of the base year, and  $Q_i$  the quantities of the given year) using the FAO Eastern European wheat-based price relatives as weights. The time comparison base period chosen in this study is the year 1965.

*Agricultural output.*—In this study agricultural output is defined as end-use output from agriculture available for human consumption and industrial use, plus changes in livestock, and farm investment in kind by farmers' own efforts. The same concepts are used by the U.N. economic organs to calculate agricultural output in Western Europe and by the OECD member countries. In this study the output of agriculture is calculated by subtracting from gross crop and animal production all intermediate products utilized on farms in further production. The physical quantities of output are then aggregated by the FAO wheat-based weights. (The weights are given with some adjustments in G. Lazarcik, *Compendium 1974*, pp. 388–389.)

*Expenses and depreciation.*—Current operating expenses are defined here as the total quantity of all goods and services bought by the agricultural sector from all non-agricultural sectors and from abroad and used up in the production of agricultural output. Depreciation is here defined and calculated as the current charge to take account of wear, tear and obsolescence of capital goods serving agriculture. (See U.N. Economic Commission for Europe, *Agricultural Sector Accounts and Tables, A Handbook of Definitions and Methods*, Geneva, 1956, p. 10, and Organization for European Economic Cooperation, *The Measurement of Agricultural Production and Food Consumption*, Paris, 1955, p. 15.)

*Gross product and net product.*—The gross product of agriculture is the gross value added by productive activity within the agricultural sector. It is the contribution of the agricultural sector to gross national product (GNP). In this study it is obtained from agricultural output by subtracting current operating expenses. The net product of agriculture is the gross product minus depreciation. It is the contribution of the agricultural sector to the net national product (NNP) or net value added by the agricultural sector. For the years after 1970, the expenses, gross and net product were calculated by a short cut method described in detail in *OP-48*, pp. 74–93 and *OP-49*, notes to tables 1 to 6.

# RECENT DEVELOPMENTS IN ORGANIZATION AND MANAGEMENT OF AGRICULTURE IN EASTERN EUROPE

BY EVERETT M. JACOBS\*

Horizontal integration.....	342
Vertical integration.....	351
Conclusion.....	355

Since the end of the Second World War, Eastern European agriculture has gone through a number of phases of development that have encompassed virtually the whole area. The late 1940s and early 1950s saw the collectivization of agriculture along Soviet lines in most Communist countries. This process was for the most part completed by the early 1960s, although by then Yugoslavia and Poland had abandoned collectivization as a policy. The next phase was a movement, continued to the present, to amalgamate small farms into larger units in order to improve central control, facilitate mechanization, reduce administrative staff, and, it was hoped, benefit from the economies of scale. The mid and late 1960s saw the introduction of economic reforms in East European agriculture in an effort to improve efficiency, primarily through the use of economic incentives (mainly in price policy and bonuses), simplified central control, and greater agricultural investments.<sup>1</sup>

The current phase of development in East European agriculture involves revisions and modifications to the economic reforms.<sup>2</sup> At the same time, it includes attempts, dating from the early 1970s, to introduce some form of economic integration between farming enterprises and/or between agriculture and industry. The purpose of this study is to examine recent developments in the organization and management of the socialist sector of agriculture, especially as they relate to agricultural integration, in Bulgaria, Czechoslovakia, East Germany, Hungary and Rumania.<sup>3</sup>

\*The author gratefully acknowledges the financial support received from the Knoop Economics Research Fund of the University of Sheffield in this research.

<sup>1</sup> For further details, see Everett M. Jacobs, "Ownership and Planning in Soviet and East European Agriculture," in Peter J. Wiles, ed., *The Prediction of Communist Economic Performance* (London, 1971), pp. 39-86.

<sup>2</sup> See Everett M. Jacobs, "Organization and Management of Agriculture in Eastern Europe, 1967-1974," in Zbigniew M. Fallenbuchl, ed., *Economic Development in the Soviet Union and Eastern Europe, Volume 2: Sectoral Analysis* (New York, 1976), pp. 284-305.

<sup>3</sup> Poland and Yugoslavia have been omitted because of the minor role of the socialist sector of agriculture in those countries; Albania, because of scarcity of information.

## FARM SIZES

It is clear from Table 1 that changes in the number of state or cooperative (collective) farms in Eastern Europe in recent years have had little or no effect on the proportion of each country's arable area occupied by one or the other kind of farm, except in Bulgaria and, within the cooperative sector, East Germany. In Bulgaria, the decision in November 1973 to make the agro-industrial complex (APK) into the basic economic and social organization in the countryside<sup>4</sup> has in practice all but negated the significance of cooperative and state farms. As explained below, the APK is a form of horizontal integration which unites cooperative farms, state farms, or both cooperative and state farms. In the first stage, the constituent farms retain much of their former independence. However, as the APK develops, responsibilities are transferred to the APK management, which eventually assumes full legal and economic control over all member farms of the complex.<sup>5</sup> When an APK becomes "unified", the component farms lose their autonomy and become branch or sub-farms of the APK. By the end of 1975, 83 APKs, or more than half the total number, had become unified,<sup>6</sup> meaning that many of the existing state and cooperative farms were no longer separate economic units. In 1974, the APKs and other forms of integration accounted for 84.5% of the country's arable area, seemingly indicating that not all the cooperative and state farms were yet members of complexes.<sup>7</sup> Before the creation of the complexes, Bulgarian state and cooperative farms had always been among the largest in Eastern Europe, but now, in the form of APKs, averaging almost 21,500 ha. of arable land, they are six times the size of Soviet collective farms (which in 1975 averaged 3,571 ha. of arable land) and 3.3 times the size of Soviet state farms (6,494 ha. of arable land). The Bulgarian experiment is therefore of obvious interest to the other Communist countries.

<sup>4</sup> *Ekonomika sel'skogo khozyaistva*, no. 11 (1974), p. 115.

<sup>5</sup> Paul Wiedemann, "The Organisation of Bulgarian Agriculture," a study forming part of the Ford Foundation Project on "The Organisation and Comparative Efficiency of Soviet and East European Agriculture" (Glasgow, 1976), mimeograph, p. 19.

<sup>6</sup> *Novo Vreme*, no. 2 (1976), p. 43.

<sup>7</sup> The socialist sector covered 90.3% of arable land in Bulgaria in 1972 (Jacobs, "Organization and Management . . .," *op. cit.*, p. 285). The missing 5.8% of arable land presumably belongs to farms which have not yet joined APKs.

<sup>1</sup> Including personal plots of farm members figures for East Germany related to agricultural land.

<sup>2</sup> Workers only.

<sup>3</sup> All of these farms are members of agro-industrial or industrial-agricultural complexes, and as a result, many have lost their economic and administrative independence.

<sup>4</sup> Data relate to agro-industrial and industrial-agricultural complexes, not farms.

<sup>5</sup> Not including independent MTS work force.

<sup>6</sup> Including tractors owned and operated by MTS (or equivalent).

<sup>7</sup> Based on country's entire arable area and total agricultural tractor park (15-hp units).

<sup>8</sup> Hectares agricultural land (all sectors) per physical tractor unit.

<sup>9</sup> As of Jan. 1, 1976.

<sup>10</sup> Excluding lower level cooperatives in Czechoslovakia and Hungary, and gardening cooperatives (GPG's) in East Germany.

<sup>11</sup> Including apprentices.

<sup>12</sup> Excluding apprentices.

<sup>13</sup> 1973.

In East Germany, the past few years have seen the rapid diminution, in terms of number and area, of the lower type cooperatives through their upgrading to Type III cooperatives, which resemble Soviet collective farms. The campaign against lower type cooperatives has been a feature of East German agriculture since the mid-1960s, and it now appears that lower type cooperatives will pass from the scene in the next few years. Between 1972 and 1974, the number of lower type cooperatives fell from 1,939 to 698, and their share of agricultural land, from 7.8 percent to 3.5 percent.<sup>8</sup> Because of gains in agricultural area from the upgraded lower farms (almost 1¼ million hectares since 1967), and because of simultaneous amalgamations, the Type III cooperatives have significantly increased in size. The average size of East German state farms has grown also as a result of amalgamations, but they remain by far the smallest state farms in Eastern Europe.

The data in Table 1 unfortunately do not give a clear indication of the scope of the recent amalgamation campaigns in Czechoslovakia and Hungary. In Czechoslovakia, amalgamations of farms have been accompanied by efforts to complete the collectivization of the central areas of Slovakia. The collectivization campaign in Slovakia between the end of 1971 and the end of 1975 added 140,529 ha. of agricultural land, of which 27,449 ha. were arable land, to the cooperatives of that republic. In the same period, concurrent amalgamations caused the number of cooperatives in Slovakia to fall from 1,774 to 991. By contrast, between the end of 1971 and the end of 1975, the number of cooperative farms in the Czech lands fell from 4,097 to 1,825 because of amalgamations, but the area they encompassed hardly grew. Looking at Czechoslovakia as a whole, the number of cooperative farms dropped by 883, to 2,736, between the end of 1974 and the end of 1975 because of amalgamations. At the end of 1975, the average arable area of a cooperative farm in Czechoslovakia was 1,199 ha. (1,233 ha. in Slovakia, and 1,182 ha. in the Czech lands). The number of state farms in Czechoslovakia also fell significantly in 1975 because of amalgamations. In the Czech lands, the number of such farms dropped by 39, from 213 to 174, while in Slovakia, the loss was only 1 farm. At the end of 1975, there were 250 state farms in Czechoslovakia, averaging 3,988 ha. of arable land (2,974 ha. in Slovakia, and 4,431 ha. in the Czech lands).

Since 1970, amalgamations have been officially encouraged only for relatively small cooperatives in Czechoslovakia, originally with less than 500 ha. of agricultural land, but recently with less than 1,000 ha.<sup>9</sup> Amalgamations were viewed as especially suitable in mountainous regions and where cooperatives were too small to warrant the introduction of large-scale production technology. Other cooperatives were supposed to create larger production capacities and a higher degree of specialization not by amalgamations, but by entering into cooperation schemes with other farms. However, many cooperative farms, not only the small ones, prefer to merge with neighbouring cooperative farms in order to avoid the complications of the new cooperation projects which, according to one expert, are

<sup>8</sup> *Ibid.*

<sup>9</sup> Vladislav Bajaja, "The Organisation of Czechoslovak Agriculture," a study forming part of the Ford Foundation Project on "The Organisation and Comparative Efficiency of Soviet and East European Agriculture" (Glasgow, 1976), mimeograph, p. 25.

now more or less forced upon them from the center (see below).<sup>10</sup> This partly explains the wave of cooperative farm mergers in the 1970s, especially in 1975. Pressure from Party and government officials undoubtedly also contributed to the farm amalgamations in 1975, as a second-best solution to the problem of encouraging cooperation between farms.

The campaign to merge state farms in the Czech lands in 1975 may also have been due to a desire to avoid entanglements in cooperation projects. On the other hand, although the state farms were already large before the amalgamations, they might still have been too small to undertake projects meeting the government's criteria for the establishment of new livestock enterprises to satisfy the country's meat requirements. The "optimal" capacities for such new livestock projects are quite high: over 500 head for milk cows, over 700 head for calves, over 500 head for heifers and for bullocks and young fattening cattle, over 600 head for sows, and over 4,000 head for fattening pigs.<sup>11</sup> It is also possible that the amalgamation campaign may have been motivated by a desire to create state farms with a higher degree of territorial consolidation. At present, most state farms lack this, being composed of several sub-divisions (sub-farms), in many cases located among neighbouring cooperative farms.<sup>12</sup> Such fragmentation of course hinders the efficient use of resources. As in the case of the cooperative farms, it is evident that the mergers were done with official approval, if not under official orders.

In Hungary, as in Czechoslovakia, the official policy in the early 1970s had been to develop forms of cooperation between farms to aid in the concentration of production, rather than to merge farms in places where personnel and material conditions were inadequate.<sup>13</sup> All the same, the number of cooperative farms in Hungary decreased by 403 between the end of 1972 and the end of 1974 (to stand at 1,918) because of amalgamations, and at the start of 1975, it was announced that the number of cooperatives would fall to 1,600-1,620 by the end of the year through "voluntary" mergers.<sup>14</sup> As in Czechoslovakia, the idea was to reduce or eliminate the number of small cooperatives farming under 1,000 ha. of land, and to reduce the number farming between 1,000-3,000 ha. The average post-merger cooperative was to have about 3,000 ha. of agricultural land, but many would have 5,000-6,000 ha. or more. The goals of the amalgamations were to produce better economic conditions on the enlarged farms by avoiding duplication, increasing the sums available for capital investments, increasing productivity through the introduction of new technology, creating better opportunities for ancillary activities, and freeing agricultural specialists from administrative work for production work. The mergers were to proceed only where the objective preconditions existed,<sup>15</sup> but within days of the start of the campaign, it was announced that Party and government functionaries were resorting to pressure to encourage mergers.<sup>16</sup>

<sup>15</sup> *Ibid.*

<sup>16</sup> Radio Budapest, 25 January 1975.

Even though the mergers were being carried out under official auspices, matters appeared to be getting out of hand by the end of September 1975. It seems that some organizations were planning a new wave of farm amalgamations,<sup>17</sup> and an order went out, effective from 5 October, that the approval of the Ministry of Agriculture and Food would be necessary for further mergers.<sup>18</sup> At the end of 1975, there were 1,599 cooperative farms in Hungary, each covering an average of 3,538 ha. of agricultural land, an increase of 20.8 percent over the previous year. In spite of prohibitions, mergers continued at a rapid pace at the start of 1976, allegedly because of overzealousness by local Party and government officials.<sup>19</sup> By September 1976, there were only 1,462 cooperatives, and the number of state farms had fallen to 134.<sup>20</sup> In December 1976, Kadar stated at the Third Congress of Agricultural Cooperatives that the cooperatives created through the amalgamations were large enough. He re-emphasized that instead of further mergers, the cooperatives should expand cooperation among themselves, especially through agro-industrial associations.<sup>21</sup>

As a result of the amalgamations in the course of 1975, the proportion of Hungarian cooperatives with up to 3,000 ha. of agricultural land fell from 77.4 percent to 55.6 percent, the proportion with 3,000–5,000 ha. rose from 15.4 percent to 31.4 percent, and the proportion with more than 5,000 ha. grew from 2.6 percent to 13.1 percent. However, it soon became apparent that the farms were unable to make efficient use of the larger areas, since they lacked the necessary trained personnel, new buildings, equipment, and machinery. The emphasis placed on new facilities encouraged a construction "fever" in mid-1975, with farms putting up new animal-breeding and keeping buildings while the old ones stood empty. Also, many exaggerated investment demands were made by the enlarged farms.<sup>22</sup> In short, conditions had not been objectively ripe for the ambitious amalgamation campaign of 1975 and 1976. That amalgamations were forced on the farms suggests that the government was impatient with the slow progress made towards cooperation among farms, and decided to try to foster concentration and specialization through administrative means.

In contrast to the other countries, Rumania appears to have remained cautious over the further amalgamations of farms. This is a result of the lessons learned from the fiasco of 1971 when, within a year, the number of state farms was reduced from 370 to 200, only to rise again to 364 on the grounds that many of the enterprises were too large, causing management problems.<sup>23</sup> In spite of the loss of some arable land in recent years, Rumanian state farms are still the largest on average in Eastern Europe, and the cooperatives are larger than those in most other countries.

#### MECHANIZATION AND FERTILIZER CONSUMPTION

As seen in Table 1, the level of mechanization has improved in Eastern Europe in recent years, especially in Bulgaria, Hungary, and

<sup>17</sup> Radio Budapest, 11 October 1975.

<sup>23</sup> Jacobs, "Organization and Management . . ." *op. cit.*, p. 286.

Rumania. The difference in level of mechanization between Rumanian state and cooperative farms is still great, at a time when such gaps appear to have been eliminated in the other countries under consideration, and is part of Rumania's general policy to give preference to the state sector. It should also be added that more than 70 percent of Rumanian-produced tractors are exported in order to balance trade, earn foreign exchange, and meet obligations to Comecon countries.<sup>24</sup> Were it not for that, Rumania's level of mechanization would be considerably higher. In East Germany, the number of tractors in socialist agriculture reached a high point in 1972, and has declined slightly every year since. It would appear that the East German policy is now to replace worn-out tractors, although without increasing the size of the total tractor park. All the other East European countries are still trying to increase the size of their tractor parks.

A continuing problem in Eastern Europe is the lack of adequate spare parts and repair facilities, which tend to keep machinery out of service for long periods. For example, in Hungary in 1973, 3,000 out of 13,000 combine harvesters were unusable because of lack of spares.<sup>25</sup> Efforts are currently being made throughout Eastern Europe to reduce this problem, including through the cannibalization of old machinery for spares, but it appears that a permanent solution is still many years away.

The development of sophisticated production systems for certain crops, particularly in Hungary and East Germany, but also elsewhere, is increasingly shifting the emphasis of mechanization to the acquisition of specialized machinery. Hungary's factories have ceased production of tractors, wheat combines, and large capacity automatic machinery, making the country dependent on foreign suppliers for advanced equipment. The Soviet Union and East Germany have shown themselves incapable, or perhaps unwilling, to deliver to Hungary the quantity and variety of tractors, combine harvesters, and systems equipment required,<sup>26</sup> and therefore Hungary is making large-scale purchases from Western suppliers. In 1974, Hungary planned to spend \$10 million on the purchase of spare parts and \$30 million for the purchase of new systems of equipment from Western firms.<sup>27</sup>

East Germany appears to have been able to get specialized equipment from the Soviet Union, and has developed pooling arrangements for several cooperative and state farms to use the same modern machinery and systems of machines. In 1974, about one-quarter of the cooperative farms participated in such pooling arrangements.<sup>28</sup> The idea has been to create cooperation units of 3,000–6,000 ha. in order to use profitably the E512 combine harvester complex (which requires at least 2,000 ha.) and the Soviet Krovez K700 all wheel tractor (which needs an area of 6,000 ha.).<sup>29</sup> With such expensive and complex equipment, the problems of spares and maintenance becomes even more important than before, and should present most Com-

munist countries with considerable difficulties, at least in the short term.

In the period between 1967 and 1974, the level of consumption of mineral fertilizer changed considerably in Eastern Europe. East Germany further increased consumption to 395 kg. of pure nutrients per ha. of arable land, followed by Czechoslovakia with 316 kg. (a rise of 71.7 percent). Hungary's fertilizer application jumped 2.7 times in the period, while Bulgaria's fell slightly. Rumanian fertilizer consumption is still the lowest in Eastern Europe, and is further distinguished by the wide gap in fertilizer application between state farms (132.6 kg./ha. of arable land in 1973), and cooperative farms (69.2 kg./ha.).<sup>30</sup>

Hungary's increased consumption of fertilizers has been made possible by large imports from Comecon and Western countries. The Hungarian fertilizer industry produces about 50 percent of the country's requirements, with 30 percent coming from Comecon partners, and 20 percent from Western sources.<sup>31</sup> Until the start of 1976, the increased costs of fertilizer and other chemical imports were subsidized by the government. However, the government decided to increase the price of fertilizers by 23 percent in 1976 in order to lessen the subsidy, discourage wasteful practices in the storage and handling of fertilizers, and encourage farms to use their sizeable stocks of manure to better advantage.<sup>32</sup>

Certain upward adjustments were made to procurement prices at the same time to cushion the farms. Nevertheless, cooperatives reacted by cutting back on fertilizer purchases in an attempt to maintain farm profitability, especially after it was seen that the 1976 drought would reduce yields. Long-term as well as short-term credits for the purchase of fertilizer were offered to reverse this trend,<sup>33</sup> but fertilizer purchases by cooperatives in the first nine months of 1976 were still 8 percent below the corresponding figure for 1975.<sup>34</sup> This of course jeopardized further production advances, especially for cereal crops, thereby possibly lessening Hungary's cereal export trade which was helping to finance the mechanization program. Although Hungary appears to be more badly hit by the price rise for fertilizers than many of the other Communist countries, there is evidence to suggest that the rate of increase in fertilizer consumption by the East European countries will be slower in the next few years than in the past.

#### TRANSFER OF LABOR AND LABOR PRODUCTIVITY

The mechanical and technical improvements in East European agriculture in recent years have facilitated the transfer of labor from the rural areas to the industrial centers, to the extent that there are now often labor shortages at peak farming periods and even at other times of the year. The agricultural work force of Bulgaria fell by about 310,000 persons between 1967 and 1974 (24.7 percent). During same period, the agricultural labor force fell by 179,000 in Czechoslo-

<sup>30</sup> The figure for fertilizer consumption by cooperatives excludes the area covered by the personal plots of cooperative farmers. In 1967, fertilizer consumption was 97.0 kg./ha. of arable land for state farms, and 42.0 kg./ha. for cooperative farms.

<sup>31</sup> *Magyar Mezőgazdaság, Információk*, 14 August 1974.

<sup>32</sup> *Figyelem*, 10 November 1976.

<sup>33</sup> *Magyar Hírlap*, 25 August 1976.

<sup>34</sup> *Figyelem*, 10 November 1976.

vakia (15.3 percent), and by almost 189,000 in East Germany (16.2 percent). Between 1970 and 1974, about 131,000 left Hungarian agriculture (a fall of 11.0 percent), and the decline was also substantial in Rumania, although some of the statistics, given as they are in families in the cooperative sector, leave the extent of the decrease open to conjecture.

Such losses of manpower have made increases in labor productivity all the more important in East European agriculture. For the period 1970-1974, as compared with 1965-1969, labor productivity in state and cooperative farms rose by 44 percent in Hungary, 42 percent in East Germany, 37 percent in Bulgaria, and 22 percent in Czechoslovakia. By contrast, the figure for the USSR was 28 percent.<sup>35</sup> Output per farmer has been consistently higher in the state sectors than in the cooperative sectors because of the greater degree of overall mechanization and the longer hours worked by farmers in the state sectors.<sup>36</sup> As seen in Table 2, labor productivity judged on an hourly basis is for the most part also higher in state farms than in cooperatives, except, for unexplained reasons, in Bulgaria. However, the rate of growth of labor productivity in cooperative farms is higher than in state farms, and East European planners foresee that the difference will eventually be eliminated, as they have been to a major extent in East Germany.<sup>37</sup>

Although the improvements in agricultural labor productivity are commendable, it must also be said that labor productivity in agriculture is far below that in other spheres of the East European economies. A recent study has shown that in 1974, labor productivity in agriculture and forestry, as a percentage of labor productivity in the rest of the economy (i.e., the whole economy, minus agriculture and forestry,

<sup>35</sup> V. Masenkov, O. Cherkasheninova, and V. Gabidullin, "Proizvoditel'nost' truda v stranakh-chlenakh SEV," *Ekonomika sel'skogo khozyaistva*, no. 2 (1977), p. 116.

<sup>36</sup> *Ibid.*, p. 117.

<sup>37</sup> *Ibid.*, p. 115.

and minus the non-productive sphere) stood at 48 percent in Bulgaria, 45 percent in Czechoslovakia, 70 percent in East Germany, 52 percent in Hungary, only 24 percent in Rumania, and 52 percent in the USSR.<sup>38</sup> The low level of agricultural productivity when compared with other sectors of the economy is due fundamentally to the low level of capital per worker in agriculture. Only in East Germany has the share of fixed capital in agriculture (excluding land) reached a level roughly equal to that in the labor force, and this is the main reason why the disparity in labor productivity is smallest in that country.<sup>39</sup> One of the main motivations behind the plans for agricultural integration in Eastern Europe is to maximize the effectiveness of available capital inputs in order to increase output and also labor productivity.

#### HORIZONTAL INTEGRATION

Attempts to achieve the concentration and specialization of agricultural production in Eastern Europe have been hindered by a number of factors. Even though the cooperative and state farms were large by West European standards, they often lacked the capital, material resources, and labor resources to make large-scale agricultural production projects feasible. Moreover, most farms were prevented from specializing because of their more or less compulsory contractual obligation to deliver a wide range of products to procurement agencies. For example, until the full-scale introduction of APKs, most Bulgarian cooperative farms were producing between 50 and 60 different crops and several different kinds of farm animals.<sup>40</sup> The most typical attempts to solve these problems involved the merger of farms into larger production units, increases in prices paid to farms (in the hope that they would then operate profitably and be able to accumulate investment capital), and offers of certain credits for the construction of new facilities. However these efforts usually did not encourage specialization, nor did they lead to the desired concentration of production, since financial, technical, and labour resources and management techniques were still inadequate. The different forms of agricultural integration introduced in Eastern Europe in recent years have been designed to circumvent these problems.

In general terms, horizontal integration implies greater financial and economic cooperation and coordination between farms in production work and product specialization. Farms operating under similar conditions are brought together in some form of association or complex, which then becomes integrated within itself. Some types of association or complex will process, as well as produce, a given agricultural product, but in horizontal integration schemes, there is no integration between the association or complex and related industrial processing enterprises or sales organizations. By contrast, in vertical integration schemes the already integrated agricultural sector becomes fully integrated with the industrial sector relating to it so that the whole economic process, from producing the primary product to selling the final product, is the responsibility of a single corporate unit. The eventual goal of vertical integration is to make agriculture into a branch of the food industry and light industry.<sup>41</sup>

<sup>38</sup> Karl-Eugen Wädek, "The Place of Agriculture in the European Communist Economies: A Statistical Essay," *Soviet Studies*, no. 2 (1977), p. 243.

<sup>39</sup> *Ibid.*, p. 244.

<sup>40</sup> *Voprosy ekonomiki*, no. 5 (1972), p. 148.

<sup>41</sup> *Ekonomika sel'skogo khozyaistva*, no. 3 (1975), p. 116.

Horizontal integration of agriculture has proceeded farthest in Bulgaria, through the institution of the agro-industrial complex, which is supposed to introduce industrial methods and technology to farming. Bulgaria is the only Communist country to have introduced horizontal integration on a national scale. As already mentioned almost all farms in Bulgaria are members of APKs. At the end of 1974, there were 153 APKs, 9 industrial-agricultural complexes (PAKs—the basic form of vertical integration), and 2 scientific-productional associations (NPOs—another form of vertical integration). In all, membership of the APKs and PAKs amounted to 462 cooperative farms, 130 state farms, and 427 specialized enterprises. Each complex has an average of five or six cooperative and/or state farms, almost 25,000 ha. of cultivated land, around 6,500 permanent workers, more than 650 15-h.p. tractor units, and basic funds worth more than 25.3 million leva. Some complexes are much larger than average (up to 100,000 ha. and more), but some, at least in the early years, were considerably smaller than the then average size of a single cooperative (then about 5,000 ha.).<sup>42</sup> The very small APKs seem to have been disbanded or absorbed into larger APKs, as evidenced by the drop in the number of APKs from 170 in 1971 to 153 in 1974, although the agricultural area they covered was virtually the same. Each district usually has between 5 and 7 APKs within its boundaries.<sup>43</sup> In keeping with the aim of specialization, the complexes usually grow only between 3 and 5 crops, and usually limit themselves to only one branch of livestock production.<sup>44</sup>

As mentioned previously, more than half of Bulgaria's APKs have become unified, with the consequent loss of independence by the constituent farms. Unification of an APK is not supposed to occur until a certain level of concentration and specialization has been reached, and the level of labor remuneration among the member farms has been equalized. When an APK becomes unified, the form of management changes from territorial to branch (i.e., section managers become concerned with spheres of specialization rather than separate territorial units). Each previously independent farm becomes a branch or sub-farm of the APK, with its own production specialization (e.g., grain growing, livestock breeding, fodder production, fruit production, etc.). These branches operate on the principles of economic accountability within the APK.<sup>45</sup> Even when an APK becomes unified, members of constituent cooperative farms are allowed to retain their personal plots. In fact, the farming activities undertaken by cooperative members and other groups of the population on their personal plots have received considerable encouragement from the state in the past few years. For example, for fulfilling contracts for the sale to the state of specified kinds and quantities of produce from their plots, peasants receive incentives such as fodder for livestock and various premia.<sup>46</sup>

Whether or not the APK is as yet unified, the boundaries separating individual farms and fields sown with different crops are abolished, and very large fields, called "massives", sown to a single crop are created. Before the establishment of APKs, grain was grown in

<sup>42</sup> *Rabotnicheskoe Delo*, 22 September 1970.

<sup>43</sup> *Ibid.*

<sup>44</sup> *Voprosy ekonomiki*, no. 5 (1972), p. 148.

<sup>45</sup> V. Aref'ev and I. Karpenko, "Spetsializatsia v ramkakh sotsialisticheskoi integratsii", *Ekonomika sel'skogo khozaystva*, no. 3 (1977), p. 109.

<sup>46</sup> *Rabotnicheskoe Delo*, 16 March 1974.

Bulgaria in more than 75,000 fields, each with an average area of 40 ha. In 1976, the size of grain fields ranged from 200 to 500-1,000 ha. Up to 1970, vegetable crops were grown in 17,000 fields, but in 1976, production was concentrated on basically 260 fields, averaging 315 ha. each.<sup>47</sup> Fruit and grape plantations now have from 1,000 to 2,500 ha., and concentration has also proceeded in the production of sugar beet, rice, cotton,<sup>48</sup> maize, sunflower seed, tobacco, and other crops.<sup>49</sup> In the livestock sector, developments have been equally noteworthy. At the start of 1976, 11 APKs for fattening calves had 3,000-11,000 calves each, 13 poultry APKs had 3-6 million broilers each, 9 egg APKs had 100,000 hens each, and 18 pig-breeding APKs put through 32,000-100,000 pigs per year each.<sup>50</sup>

Events in the district of Silistra give a good indication of the operation of APKs and also point to possible future trends. In the spring of 1974, the district's 6 existing APKs were merged into two complexes. One was a unified APK, having 21 cooperative and 2 state farms, and specializing in grain growing and livestock breeding. Management was on the branch principle (one branch for each specialization). The second complex involved vertical integration. The new complex became a fruit and vegetable growing PAK attached to the Rodopa Economic Concern. It had 7 cooperatives and 1 state farm, and 2 canning factories. The component farms lost their economic independence, and management was on the branch principle.<sup>51</sup> In February 1976, the APK and PAK were merged to form a single APK (n.b., the PAK was completely eliminated),<sup>52</sup> covering almost all the land of the district (153,000 ha. out of 173,000, of which the pre-merger APK contributed 124,400 ha.), and about 3.5 percent of Bulgaria's agricultural land.<sup>53</sup> This super-large APK was to specialize in "output of agricultural production and the processing of fruit and vegetables", thus combining some of the features of the old PAK with the new APK. Approval for the merger of the APK and PAK was given only after a U.S. firm was awarded a contract to direct the operation.<sup>54</sup> The Bulgarians reportedly hoped that foreign expertise and technology would help to overcome some of the problems in feed-livestock production, including fluctuating production and profitability, the need for heavy investment in new storage facilities, and vast new irrigation facilities. Such investments are now under constraint in Bulgaria. The agreement called for Bulgarians to pay for the investments, technology, and management services principally in products.<sup>55</sup> Success in this venture may make the way for the creation of super-large APKs throughout Bulgaria.

Until recently, it appeared that there was a certain amount of flexibility and local decision-making in APKs. However, whatever give there was to the system in the early years has now vanished. For example, a national APK was formed in September 1976 to act as an overlord in unified state policy in the sphere of agriculture and

<sup>55</sup> Lambert, *op. cit.*, pp. 10-11.

the food industry.<sup>56</sup> Under current plans for regional specialization in both feed crops and livestock, only cattle will be raised throughout the country, although production methods are supposed to be geared to local conditions. Other livestock enterprises are to be limited to the best-suited areas, where needed grains and oilseeds can also be produced.<sup>57</sup> Individual APKs would now appear to have little say about what their livestock specialization is to be.

In annual and five-year planning, there are some chances for farms to bargain over assignments within the APK or with the planning bodies if the APK has not yet become unified. However, once an APK assumes full legal and economic control over its constituent farms, the plan targets are sent from the Council of Ministers, through the State Committee for Planning, directly to the APK.<sup>58</sup> Central control over the operations of APKs, especially unified APKs, appears to be tighter than that exerted over comparable complexes or associations in other Communist countries. With the further development of the contract system between APKs and processing, marketing, and export organizations, it is envisaged that the central allocation of control figures to APKs will be reduced.<sup>59</sup> Apart from current planning inflexibility, Bulgarian APKs must overcome the problems of high production costs (caused by the necessity of equalizing labor remuneration among the member farms),<sup>60</sup> the wide range of natural conditions encountered in one APK, the shortage of manpower, experts, and sophisticated machinery, and the general disadvantages of bigness, in order to show to the other Communist countries that the experiment is worth copying.

Rumania is introducing horizontal integration under the guidance of Inter-Cooperative Councils. Under regulations introduced at the end of December 1976, an Inter-Cooperative Council is set up in each county, and local Councils are formed within individual villages or in groups of neighbouring villages, to include the cooperative farms and the Inter-Cooperative Associations (enterprises embodying the principles of horizontal integration).<sup>61</sup> The local Inter-Cooperative Council's function is to coordinate the development plans and encourage cooperation among the cooperative farms, assist in setting up Inter-Cooperative Associations, and foster schemes incorporating a degree of vertical integration,<sup>62</sup> as discussed below. The county Inter-Cooperative Councils are responsible for working out and overseeing the county's overall agricultural production plan. In addition to allocating machinery to the cooperatives in association with the local agricultural mechanization station,<sup>63</sup> local Councils participate in the preparation of the plan indicators of the cooperatives as well as for Inter-Cooperative Associations, units of cooperative farm-state farm cooperation, and processing units of the consumer cooperatives. The Council must also check on the fulfillment of all these plans.<sup>64</sup>

<sup>63</sup> *Buletinul Oficial*, 15 April 1974.

<sup>64</sup> *Agricultura Socialiste*, 26 February 1977.

Each local Inter-Cooperative Council usually encompasses 5 to 7 cooperative farms, and includes representatives of state farming enterprises and other bodies in the locality. In mid-1973, there were 747 councils, involving all of Rumania's cooperative farms.<sup>65</sup> The average area covered by the Councils varied from 10,000–15,000 ha. in the lowlands to 5,000–10,000 ha. in mountainous areas.<sup>66</sup> The director of the local agricultural mechanization station, who is a state official, is the head of the local Council.<sup>67</sup> Although the cooperatives do not officially lose their economic or legal independence in belonging to a Council or Inter-Cooperative Association, it is obvious that they have little real autonomy.

There are two kinds of Inter-Cooperative Associations in Rumania. The so-called ordinary Association provides guidance and supervises the coordination of production.<sup>68</sup> The more important economic Inter-Cooperative Association engages in specialized production activities, e.g., poultry raising, stock breeding, vegetable production in hothouses, servicing work, and the construction and operation of production, storage, and processing facilities.<sup>69</sup> The number of Associations has continued to grow, despite the dissolution of a certain number over the years.<sup>70</sup> There were 254 Inter-Cooperative Associations in Rumania at the start of 1971,<sup>71</sup> and 412 at the beginning of February 1973.<sup>72</sup> At the end of 1973, there were 463 Associations, of which (with some duplication) 70 were for crop production, 335 for animal breeding, 66 produced some type of fodder, and 56 had other specializations. Some of the undertakings are very large, as seen from recent "optimum" sizes specified for Inter-Cooperative Associations specializing in livestock production: for hog fattening, 15,000–30,000 hogs; cattle fattening, 2,700 head (maximum); sheep fattening, 15,000 head; poultry, 600,000 broilers; and eggs, 36,000 hens.<sup>73</sup> In 1973, the agricultural production of Inter-Cooperative Associations represented about 10–12% of the value of the output from the cooperative sector.<sup>74</sup>

It is possible for Inter-Cooperative Associations to be composed of cooperative farms alone or of cooperative farms and, seemingly, one state enterprise. Where only cooperatives belong to the Association, the chairman is the director of the local agricultural mechanization station. An Association occasionally includes a state enterprise (usually a state farm) as a member, in which case the director of the enterprise becomes the Association's chairman.<sup>75</sup> Thus, the Association always has a state employee exercising control over its activities. An Inter-Cooperative Association usually has 4 or 5 cooperative farms as members, but some, depending on the character of the activities, may involve 20 or 30,<sup>76</sup> or even 40 to 50 farms, sometimes 100 to 150 km. apart.<sup>77</sup> Some cooperative farms are members of 5 or 6 Associations.<sup>78</sup> Members of an Association retain their economic and legal independ-

<sup>78</sup> *Ibid.*

ence, but must contribute cash and equipment to the Associations' enterprise fund to ensure fixed assets and necessary operating capital.<sup>79</sup>

Rumanian planners are worried that the trend for Associations to involve more and more farms quite distant from each other, and for farms to be members of several Associations, weakens the objects of deep concentration and specialization. It is feared that farms do not take much interest in joint enterprises located far away, that their production interests are being diverted in too many directions at once, and that their investments are not being used to best advantage.<sup>80</sup> There have also been doubts expressed about the large size of some Associations, especially since it appears that farms join the Associations less because of economic interests than because of pressure from above.<sup>81</sup> Cooperatives are said to have reservations about the Associations because they have tended to lose money. Since the Associations are not legal persons, member cooperatives have been required to cover the losses instead of receiving additional income from their new activity.<sup>82</sup> Another problem is that the large Inter-Cooperative Associations cut across the boundaries of several Inter-Cooperative Councils, leading to problems of coordination among Councils. It would appear that the county Inter-Cooperative Councils were instituted in part to cope with this problem. It is clear that the present arrangements for horizontal integration in Rumania are extensive, but at the same time unsatisfactory in their operation. Further changes can be expected in the near future.

In contrast with most other Communist countries, where the concentration and specialization of production are to be achieved as a result of the creation of large farms and cooperation and integration projects, East Germany's integration program is being carried out after a significant degree of farm specialization has already been reached, even though (or perhaps, because) East German farms are small by Communist standards. There are now about 150 specialized crop-growing cooperative and state farms in East Germany, characterized by a high level of concentration and specialization of production, the widespread adoption of industrial methods, and close links with the processing industry.<sup>83</sup> For example, the "Jena" specialized crop cooperative near Potsdam is about 4 times the size of most Type III cooperatives, having 5,700 ha. of agricultural land. It has reduced the number of crops it grows from 12 to 5, and now devotes 19 percent of its arable land to its main specialty—seed potatoes.<sup>84</sup> Such a degree of specialization would be difficult to find in farms of similar size in other countries under discussion. Although the Jena farm is not altogether typical, East Germany has gone further to implement a program of specialization than the other countries, and this has helped in the introduction of horizontal integration.

The most widespread form of integration in East Germany involves inter-farm cooperation associations for crop production. These unite several nearby cooperative and state farms with similar economic conditions. The member farms reportedly pool their land, financial, material and labor resources,<sup>85</sup> although they retain their economic

<sup>79</sup> *Buletinul Oficial*, 15 April 1974.

<sup>82</sup> *Ibid.*

<sup>83</sup> Aref'ev and Karpenko, *op. cit.*, p. 111.

<sup>84</sup> *Ibid.*

<sup>85</sup> *Ibid.*

and legal independence. Obviously, this is possible only where conditions on the participating farms are very similar. Through the introduction of these associations, the average size of a production unit in crop production has increased from 600 ha. to 4,200 ha.<sup>86</sup> As mentioned earlier, this makes it profitable for the associations to purchase modern technology and systems of machines for crop production, which the member farms then share. There are now about 1,200 of these associations, cultivating about 90 percent of the country's agricultural land. Each inter-farm association covers from 4,000 to 6,000 ha. of agricultural land (from 3 to 10 farms).<sup>87</sup>

In recent years, inter-farm cooperation associations have also developed rapidly in East Germany's livestock sector. There are currently 394 such enterprises, occupied in milk production, hog and cattle fattening, heifer rearing, and poultry and egg production.<sup>88</sup> In order to encourage the construction of livestock complexes operating on an industrial basis, the state has provided capital investments, grants, and reduced annual interest rates on long-term loans since the beginning of 1974. Moreover, because of the high costs of building, equipping, and stocking these inter-farm enterprises and running them in, the state also pays bonuses for produce from the complex for the first three years of its operation if the complex meets minimum capacity standards.<sup>89</sup> For example, to receive the special benefits and incentives, all newly constructed units must have a minimum of 2,000 cows in a dairy complex, 16,000 animals in a cattle fattening complex, 2,000 heifers in a heifer fattening complex, an annual volume of 25,000 tons slaughter weight (undertaking the whole cycle of production) in a hog fattening complex, 600,000 broilers, or 700,000 laying hens.<sup>90</sup> It is reported that there are now in operation hog fattening complexes with 108,000 hogs each (and one for 216,000 head is being built), cattle-fattening complexes with around 18,000 steers each,<sup>91</sup> and heifer fattening complexes with 5,000 animals.<sup>92</sup> Of the 3,800 million eggs produced in East Germany in 1973, 50 percent came from chickens kept under industrial type conditions in modern battery coops.<sup>93</sup>

Cooperation associations are also set up between East German farms for the joint performance of such tasks as melioration, chemicalization, plant protection work, construction and operation of warehouses and mixed feed plants, etc.<sup>94</sup> There is also a network of about 260 agronomic centers and more than 150 machinery servicing enterprises, with economic links with the inter-farm cooperation associations as well as individual cooperative and state farms.<sup>95</sup> Since East German inter-farm cooperation associations are not economic bodies in the eyes of the law, the plans of the member farms are coordinated with government agencies which then confirm them, and relations between members are governed by contracts they conclude with each other.<sup>96</sup> This restricts the autonomy of the associations and the

farms, although, it would seem, not as much as arrangements in Bulgaria and Rumania. The relatively small size of East German farms and inter-farm cooperation associations has helped to maintain a degree of flexibility in the system.

As seen above, the Hungarians have attempted to use the amalgamation of farms as one method to achieve concentration and specialization of production. However, it has been found that in Hungarian conditions, the value of output per hectare does not grow with farm size, and production cost per unit does not decline accordingly. In short, the enlargement of farm enterprises has not led to improved efficiency,<sup>97</sup> nor on its own has it benefited production concentration or specialization. Where Hungary has been able to move forward in these spheres has been with the introduction of the Closed Production System (CPS). The CPS is a form of horizontal integration designed to introduce the most advanced technology and industrial methods to the production, and sometimes also the processing, of certain agricultural products. In 1974, there were 91 such production systems in operation in Hungary, of which 15 were for crops, and 46 for livestock production.<sup>98</sup> The CPS is most widespread in the production of maize (535,000 ha. in 1974), sugar beet (28,000 ha.), alfalfa (17,000 ha.), and rice (13,000 ha.) in the crop sector,<sup>99</sup> and poultry production in the livestock sector.<sup>1</sup> It has also been introduced for wheat, potatoes, soya and paprika.<sup>2</sup>

The organizer of the CPS is as a rule a large leading enterprise which through contracts unites a number of farms providing land area, production facilities, and labor force. The member farms retain their basic independence, but agree to follow the instructions of the chief enterprise regarding the CPS. It is clear that the degree of central control here is far less than in other schemes for horizontal integration. The chief enterprise provides participating farms with equipment, machinery, spare parts, seeds, fertilizers, and herbicides. The organizing farm also works out the technology of production, organizes the training of personnel, sees to technical services, etc. In return for this help, the beneficiary farms pay the chief enterprise a defined percentage commission from the additional harvest received by the farms after the introduction of the system. A CPS for maize production on the base of Nadudvar cooperative began in 1973, uniting 10 co-operatives with 10,500 ha. of maize. In 1975, it had 234 members, and CPSs had also been introduced for sunflowers (25,000 ha.), sugar beets (26,000 ha.), and soya (3,000 ha.), in addition to maize (125,000 ha.).<sup>3</sup> The Babolna Joint Maize Enterprise has a similar history. Maize production by the CPS method in Hungary covered 953,000 ha. in 1975, and is planned to reach 1,600,000 ha. in 1980.<sup>4</sup>

A great problem in the introduction of the CPS has been the shortage of hard currency to buy the required machinery, equipment, and other inputs from Western suppliers. As stated above, Hungary has

been unable to depend on its Comecon partners, and does not produce the necessary machinery, or enough chemicals and fertilizers, itself. Moreover, the drain on resources caused by the recent amalgamation campaign has slowed development of CPSs. Last, the government's recent attempt to transfer an additional part of the cost of the CPSs to the farms through increased charges for fertilizers and chemical agents has inhibited the expansion, and full efficiency, of the system. Although net income tends to remain stagnant using the CPS, the great benefit is that it helps yields to increase,<sup>5</sup> which has enabled Hungary to once again become a net exporter of grain, thereby earning needed foreign currency.<sup>6</sup>

There are two basic forms of agricultural cooperation in Czechoslovakia: the cooperative association, where no new organization is created, and the tasks cannot be separated from the agricultural work of the farms involved; and the joint agricultural enterprise, where a new legal entity is created (although the member farms retain their economic and legal independence) to carry out an agricultural or non-agricultural activity. In July 1973, some 1,722 socialist farms (including 1,480 cooperatives) belonged to 387 cooperative associations, about 1/3 of which dealt with the joint use of machinery.<sup>7</sup> Very few of these associations (less than 6%) were involved in much favoured so-called complex co-operation, entailing the common cultivation of fields in inter-connected crop rotation schemes without respect of farm boundaries.<sup>8</sup> The failure to introduce complex cooperation on a large scale appears to be a reason behind the recent wave of farm mergers.

Czechoslovakia's joint agricultural enterprises represent a more developed form of horizontal cooperation, and have received much more emphasis than the cooperative associations.<sup>9</sup> Cooperative or state farms, or a combination, have created joint enterprises for pig fattening, egg and broiler production, and other agricultural activities such as potato and feed drying. Joint agricultural enterprises have also included construction firms, organizations for marketing fruit and vegetables, and even wine-taverns (the partners are involved in agriculture, even if the aim of cooperation has little to do with agriculture). There are also district joint agricultural enterprises, which are kinds of uniform common enterprises for the whole district, with several production and service branches.<sup>10</sup>

By 1 July 1975, there were 333 active joint agricultural enterprises in Czechoslovakia, of which 21 were district associations with various activities, 32 were specialized in pig fattening, 10 in egg production, 6 in cattle fattening, and 32 in feed drying and the production of feed mixtures. The majority, however, had little to do with agricultural production: 111 were purely construction or land improvement firms, 46 were agro-chemical enterprises, and 72 were engaged in unspecified other activities. Out of the total labor force of 43,652, some 30,993 worked in construction or land improvement.<sup>11</sup> The joint agricultural

<sup>5</sup> Fischer, *op. cit.*, p. 42.

<sup>11</sup> *Ibid.*, pp. 66-67.

enterprises are just beginning to make themselves felt in production, turning out 18 percent of all eggs and 10.5 percent of fattened pigs produced in 1974.<sup>12</sup> However, farms are reluctant to join joint agricultural enterprises, especially where the aim is to specialize in crop farming or in land dependent branches of animal husbandry, preferring instead to merge with another farm.<sup>13</sup> As a result, most of such schemes are imposed on the farms.<sup>14</sup>

One of the great disincentives for farms to join joint agricultural enterprises was that the tax laws seemed to penalize such participation. Until the start of January 1975, taxation was based on a cooperative farm's gross income, without reference to profits, thus giving a great advantage to profitable farms. On the other hand, taxes for joint agricultural enterprises were based on profits. Cooperatives were therefore faced with the possibility of having to give up profitable lines to joint agricultural enterprises, thereby reducing the cooperative's profitability while at the same time making it liable to higher taxes on profits from the joint agricultural enterprises operations. On 1 January 1975, a new agricultural tax law was introduced, basing taxes on land values and the profit of the farm or enterprises, eliminating the previous anomaly. Moreover, in order to promote concentration and specialization, newly established joint agricultural enterprises, such as those breeding pigs, producing eggs, fattening cattle, etc., were exempted from taxes on profits for the first five years.<sup>15</sup> It is expected that these changes will now encourage farms to participate more readily in joint agricultural enterprises. However, at present, horizontal integration is least developed in Czechoslovakia of all the countries in Eastern Europe.

#### VERTICAL INTEGRATION

In terms of vertical integration of agricultural production, the East Germans have progressed farther than the other Communist countries. The East German method has entailed the establishment of so-called cooperation unions which may involve cooperative farms, state farms, inter-farm enterprises and associations of different specializations, industrial processing enterprises, trade organizations, transport and other service enterprises, etc.<sup>16</sup> The member bodies are all supposed to be equal, but in practice, the processing enterprises predominate. All the enterprises and organizations in a cooperation union retain their economic and juridical independence, although the combine itself is a legal entity and operates under the system of economic accountability. All the members enter into contracts with each other, basing these on their centrally approved overall production plans. The contracts generally run for 2 to 3 years, after which they are revised, and non-fulfillment imposes financial penalties and legal responsibilities on the defaulter. A joint material and financial fund is maintained by the cooperation union to finance joint projects.<sup>17</sup> Cooperation unions have been formed for

<sup>12</sup> *Ibid.*, p. 67.

<sup>13</sup> *Ibid.*, p. 71.

<sup>14</sup> *Ibid.*, p. 50.

<sup>15</sup> See *Rolnische Noviny*, 26 October 1974 and *Zemelske Noviny*, 25 October 1974.

<sup>16</sup> Aref'ev and Karpenko, *op. cit.*, p. 112.

<sup>17</sup> *Ekonomika sel'skogo shozyaystva*, no. 5 (1970), p. 115-117.

meat, milk, vegetable, fruit, and jam production and processing. There were more than 380 cooperation unions in East Germany in 1975, of which more than 220 were for the production and processing of livestock products and poultry, and more than 160 were for the production and processing of vegetables, potatoes, and other crops.<sup>18</sup>

Bulgaria now has two organizations involving vertical integration in agriculture: the Industrial-Agricultural Complex (PAK), and the Scientific-Productional Association (NSO). PAKs, in contrast with APKs and NSOs, are distinguished by the predominance of an industrial enterprise in their organizational structure. Compared with APKs, the PAKs enjoy more unified planning and direction, with fewer administrative obstacles, and more concentrated capital investments.<sup>19</sup> The first PAKs were set up at the end of 1972 as constituents of the Bulgarian Sugar Industrial-Agricultural Association. This Association now encompasses 8 PAKs, including 7 sugar refineries and 1 seed farm, 3 enterprises for producing alcohol and yeast, 12 APKs, and several cooperative farms having significant areas of sugar beets. The Association's land area extends over 370,600 ha., and in its integrated economy, it produces and processes the raw material and packs it ready for sale (it does not market it itself).<sup>20</sup> Regardless of the type of farms in a PAK, the farms lose their independence to the PAK, which is classified as state property.<sup>21</sup> That the Bulgarians retain a flexible approach towards the question of relative status of APKs and PAKs is seen in the previously mentioned merger of the PAK into the APK in Silistra.

Although PAKs and NSOs seem to have similar structures and economic mechanisms, the latter are more scientifically oriented and are supposed to be set up particularly where science can be integrated with industrialized production methods. The chief enterprise in an NSO is the scientific institute. The first NSO was created for viticulture and wine production in March 1974 out of one research station, part of an existing APK (the remaining part was reorganized into a new APK), and sections of both a nearby cooperative farm and a state farm.<sup>22</sup> The main purpose of the NSO was supposed to be the introduction of innovations and technical improvements, with other aspects of viticulture and wine-making taking second place. A more ambitious NSO was set up at the end of 1976 for fruit and vegetable production and processing in Plovdiv. It has 37,000 ha. of arable land, making it much larger than the average APK, 2 scientific research institutes, an institute on the canning industry, 2 entire APKs and part of another, a number of hothouses, and other holdings.<sup>23</sup>

As previously, the land area of the NSO (unlike that of a PAK) did not form a contiguous unit. The application of science to production and processing was obviously important in the Plovdiv NSO, but its scale of operation indicates that it was set up not only for experimental purposes but also as a serious economic venture. Additional NSOs have now been created for maize production and viticulture,<sup>24</sup> and a highly integrated poultry NSO now not only

produces and processes but also markets its products.<sup>25</sup> Plans call for the creation of other NSOs for wheat, soybeans, barley, attar of roses, and other crops.<sup>26</sup> It is interesting to note that the development of the NSOs is taking place at a time when production results from the sugar industry PAKs have been disappointing. Moreover, NSOs are being introduced into a number of different production spheres, unlike the PAKs. It is likely that the NSOs will soon outnumber the PAKs, and might eventually form the basis for the further development of vertical integration in Bulgarian agriculture.

Hungary has had a number of problems in establishing vertical integration in agricultural production. There are basically three different kinds of vertically integrated combines in Hungarian agriculture: the state enterprise, in which all components are owned by the state; the joint (or inter-sectoral) enterprise, combining cooperative farms (and sometimes cooperative farms and state enterprises) under the rules relating to economic associations; and a combine-type enterprise set up by a specialist producer to process the raw material it turns out and then market the end product. In practice though, state industrial enterprises and agricultural processing enterprises have fought to maintain their monopolistic position by opposing the too rapid expansion of industrial-type ancillary enterprises by cooperative farms and the development of inter-sectoral enterprises.

Non-agricultural activity is of undoubted importance to cooperative farms, contributing 21.2 percent of cooperative income in 1973, almost half of which (9.8 percent) was from industrial activity. The practice of cooperative farms engaging in purely industrial ventures has now been greatly curtailed,<sup>27</sup> after it was found that some cooperatives had constructed airfields, operated printing works, and carried out other projects unconnected with agricultural activities.<sup>28</sup> However, some complaints have been quite unfounded, as when one industrial producer tried to stop cooperatives from fermenting their own cabbage crops.<sup>29</sup> In another case, the Milk Industry Trust tried to prohibit the marketing of dairy products produced by inter-sectoral cooperative-state associations.<sup>30</sup>

The result of this kind of opposition has been to hinder the development of industrial activity by cooperatives and the growth of vertical integration.

In 1974, Hungary had 515 joint enterprises involving cooperative farms, of which 265 were independent enterprises.<sup>31</sup> However, about 80 percent of these enterprises involved only cooperative farms, and were not truly speaking inter-sectoral enterprises.<sup>32</sup> Most of the associations dealt with construction and marketing, and only 15 percent were in any way agricultural.<sup>33</sup> Apart from the problems mentioned, cooperatives are disinclined to enter into inter-sectoral enterprises because such bodies come under tax laws relating to state enterprises, which are disadvantageous to cooperatives. Moreover many Hungarian cooperatives lack sufficient capital to participate in joint

<sup>32</sup> Fischer, *op. cit.*, p. 41.

<sup>33</sup> *Nepszabadsag*, 10 April 1975.

enterprises.<sup>34</sup> For their part, some directors of state enterprises fear that state funds will be dissipated in enterprises involving cooperatives. Faced with these obstacles, cooperatives have tended to establish their own processing plants and other ancillary industrial activities.<sup>35</sup>

In export branches of agricultural production, state-owned enterprises have formed vertically organized combines in Hungary. For example, the Tokaj Wine Combine operates as an independent enterprise, subject only to the direct supervision of the Ministry of Agriculture and Food.<sup>36</sup> It processes its own grapes (about 40 percent of the total it processes) and purchases the production of nearby cooperative farms and cooperative farm members. The Combine sells its wine through the usual wholesale, retail, and export channels, but also has its own network of shops for the sale of wine and grapes.<sup>37</sup>

In March 1975, the decisions of the Eleventh Congress of the Hungarian CP strongly favored the furtherance of joint activities of state farms, cooperative farms, and state enterprises based on contractual links.<sup>38</sup> This spurred practical developments to set up large-scale agro-industrial associations, the first of which was organized in Nadudvar in April 1976.<sup>39</sup> The association, which showed similarities to East German cooperation unions, combined on a contractual basis 14 cooperative farms, 1 state farm, and the Debrecen Poultry Processing Enterprise. The enterprises retained their economic and legal independence within the association. Under the regulations governing such associations, the cooperative and state enterprises contribute to the association from their development funds, and share in the profits in accordance with their investments. The association's operational costs are supposed to be covered by income, and part of the association's profits goes towards a social and cultural fund. Should a member decide to leave the association, the regulations provide that only the financial equivalent of the property and funds contributed at the start will be returned.<sup>40</sup> Other agro-industrial associations for vegetable production, cattle breeding, and other specializations were created in the autumn of 1976.<sup>41</sup> Some of those associations market as well as process what they produce. It is likely that increasing emphasis will be placed on building agro-industrial associations in the next few years, especially since they appear to bypass so many of the problems found in the old form of inter-sectoral enterprise.

In Rumania, the Inter-Cooperative Councils received new powers at the end of 1976 to encourage vertical integration in agriculture. The local Councils are to stimulate the development of a wide range of industrial and processing activities linking farms closely with industrial enterprises and processing units run by consumer cooperatives in the area. The Councils are also called upon to set up units for storing and partially processing vegetables, fruits, and other products. Where conditions are suitable, bakeries, butcher shops, and milk and meat processing units are to be established under local Council auspices.<sup>42</sup>

<sup>34</sup> *Magyar Hirlap*, 27 April 1973.

<sup>35</sup> Fischer, *op. cit.*, p. 41.

<sup>36</sup> *Figyelo*, 10 February 1971.

<sup>37</sup> Aref'ev and Karpenko, *op. cit.*, p. 110.

<sup>38</sup> *Nepszabadsag*, 23 March 1975.

<sup>39</sup> *Ibid.*, 27 April 1976.

<sup>41</sup> See for example *Magyar Nemzet*, 3 November 1976.

<sup>42</sup> *Agricultura Socialiste*, 26 February 1977.

It is likely that progress with such developments will be slow because of lack of sufficient investments, but it is too early to evaluate the success of the plans for vertical integration in Rumania. Vertical integration of agriculture in Czechoslovakia has made no progress to date.

#### CONCLUSION

It is clear that there is no uniform approach to the problem of agricultural integration in Eastern Europe. Bulgaria has pushed ahead, particularly with horizontal integration, to the extent that many socialist farms in that country are no longer independent economic units. East Germany has also developed integration projects, but in these, enterprise autonomy is retained. Bulgarian and Rumanian arrangements give cooperating enterprises least autonomy, whereas in Hungary, the CPS allows farms the most autonomy, in East European integration schemes. Integration has proceeded farthest in Bulgaria, and is least developed in Czechoslovakia.

Experience has shown that large production units in Communist agriculture cannot on their own guarantee the concentration and specialization of production. To be effective, integration plans must be accompanied by other measures, particularly reductions in the range of products that the production unit (whether farm or complex) must deliver and changes in management techniques. There must also be adequate investments in new machinery and technology, and sufficient numbers of trained personnel must be available. It is of course possible to impose integration plans on farms and enterprises before conditions are suitable, as is being done in some countries under discussion, but this is likely to lead to a waste of resources without achieving the anticipated benefits. Moreover, the available indications are that very big horizontally integrated enterprises are hardly more efficient than the smaller farms and enterprises they replaced. The task then for the East European countries implementing agricultural integration is not only to choose systems most suitable for their conditions, but also to improve the overall efficiency of agricultural production within the organizational framework chosen. The latter task will undoubtedly prove more difficult to accomplish in the foreseeable future.

## I: INTRODUCTION

The position and achievements of the Hungarian agricultural sector during the last decade—the period covered in this report—may be characterized by increasing specialization, growth, and efforts at increased accommodation to an altered set of external conditions. Following the major policy shift of the late 1950's, noteworthy accomplishments have been made in transforming agriculture from its relatively unfavored position of merely supporting the strategy of

\*Assistant professor of economics, North Dakota University.

super-rapid industrialization (by being the chief source of "primitive socialist accumulation") into a modern capital intensive sector with equivalent access to investment resources, technology, and innovation. The last decade (generally, the period of the New Economic Mechanism agriculture) may be viewed as a period of both consolidation and further growth: consolidation of the achievements of the "socialist transformation of agriculture" (1959-61) in which the large scale collectivization of peasant farming was completed successfully, and growth of agricultural output was accomplished primarily by means of increased use of artificial fertilizers, herbicides and insecticides, increased mechanization, and the greater application of scientific techniques and processes to agricultural production (as in the existing "closed production systems").

The period of the 1960's and early 1970's coincided with the recognition by the leadership that, within certain limits, rising consumption is not inconsistent with the expenditure of greater effort by the population and thus with future growth. Hungary experienced an uninterrupted increase in per capita real income during this period, leading to a proportionately greater demand for higher quality foods of animal origin such as pork, beef, poultry, and dairy products. The agricultural sector, in addition to generating increased foreign exchange earnings through its exports, was therefore given the task of satisfying domestic consumer needs. Years of sustained effort—in terms of increased physical inputs, technology, and appropriate economic incentives to producers—still lie ahead, however, before the "scientific agricultural revolution" is completed and agriculture becomes generally characterized by factory-type production systems and efficient interlinkages with other sectors. The successes achieved in increasing agricultural output as well as the reasons for the failures to achieve desired goals are discussed and assessed in the ensuing sections, followed by a discussion of changing agricultural policy issues, primarily as these issues found expression in the provisions of the New Economic Mechanism (NEM) pertaining to agriculture.

## II: THE ROLE AND ORGANIZATION OF AGRICULTURE

The contribution of agriculture to Hungarian national income has declined during the last decade from one-fourth in 1965 to slightly over 15 percent in 1975. The agricultural sector uses approximately 17 percent of the country's fixed assets, receives about 18 percent of annual state and cooperative investment, and employs over one-fifth of the country's work force. The share of the agricultural sector in the country's non-socialist exports is about 50 percent, down from 40 percent a decade ago.

Hungarian agricultural production takes place on state farms, collective farms or "agricultural producers' cooperatives," household plots of collective farm members, and "auxiliary" or private farms. In terms of total agricultural output and land area used, large farms—i.e., state farms and the common portion of collective farms—predominate. Nevertheless, small farms—i.e., household plots of collective farm members and private farms or gardens—have been very important in terms of their contribution to the output of selected branches of agriculture such as vegetable gardening and livestock production.

The traditional uneasy coexistence of private and public farming in socialist agricultures has undergone a basic alteration in Hungary since the late 1960's. Recognizing the difficulty and expense of expanding certain types of production—vegetable growing, dairying, pork production—on large scale farms in the socialist sector, the Hungarian government seemed to recognize early the potentialities inherent in small scale, privately controlled agriculture. The ideological imperatives of stressing the importance of "socialist" forms of production have not vitiated the pragmatic considerations of increasing domestic food supplies and foreign exchange earnings via the output of privately controlled agriculture; private plot production is classified as being in the "socialist" sector, thereby escaping the necessity for invidious comparisons.

Many of the restrictions have been removed from household plot and private production, and high officials have repeatedly exhorted collective farms to render greater assistance to household production. Between 1965 and 1968 the output of small tools and machines suitable for small scale producers tripled,<sup>1</sup> and in 1969 the restrictions concerning the number of animals that could be kept on private plots were removed.<sup>2</sup>

The last few years have been characterized by a slight decrease in the total cultivated area, primarily by state farms and household plots. Agricultural activities are pursued on a total cultivated area of 8,349 thousand hectares, of which 59.7 percent is arable land; the rest is used for gardens (1.8 percent), orchards (1.9 percent), vineyards (2.5 percent), meadows (4.6 percent), pastures (10.6 percent), and for other purposes such as forests and reeds (18.9 percent). In 1975 Hungary had 151 state farms, 1599 agricultural producers' cooperatives, 266 cooperative associations, 144 specialized agricultural cooperatives, 20 cooperative fisheries, 800 thousand household plots and approximately 120 thousand small private gardens, orchards, or vineyards. The general tendency in the socialized sector (state farms and common property of collective farms) has been the enlargement of size, while the average size of household plots and private holdings has remained roughly constant since 1965. State farms and the common property of collective farms together occupy 72.5 percent of the total cultivated land area, with household plots and private holdings together accounting for 13.6 percent (the rest of the area is made up of other state properties and uncultivated land). While the privately controlled holdings occupy only 13.6 percent of the agricultural area, their contribution to the value of agricultural output is about 34 percent. In 1975, small scale producers were responsible for 35 percent of the country's vegetables, 46 percent of its fruit, 42 percent of wine production, and over 50 percent of pork production.<sup>3</sup>

### III. AGRICULTURAL OUTPUT

As elsewhere in Eastern Europe, weather is still a major determinant of agricultural production in Hungary. Wide yearly fluctuations still occur in the output of certain crops. For instance, in 1974 a cold, rainy fall inflicted heavy damage on the grape crop, causing wine production

<sup>1</sup> *Fejer Megyei Hírlap*, October 17, 1968. Despite the increased output, however, even today there are reports of long waiting lists for certain types of machinery in this category.

<sup>2</sup> *Magyar Kozlony*, December 31, 1969.

<sup>3</sup> *Nepszabadsag*, September 10, 1975.

in that year to decline by 35 percent as compared to 1973. In 1975, flood damage reduced the wheat crop by about 20 percent. It is, therefore, more meaningful to examine average annual increases over a period of time, such as over the convenient five-year planning periods.

The value of gross agricultural output increased generally according to plans during the last two quinquennia. The third Five Year Plan (FYP) period (1966-70) called for an average annual rate of increase of 2.6-3 percent; the rate reportedly realized was 2.8 percent. During the fourth FYP period (1971-75), the reportedly realized output increase of 3.4 percent exceeded the planned rate of 2.8-3 percent. During both FYP periods the output of food processing grew at a higher rate than did raw agricultural output. As usual and as expected, both agricultural output and the output of the food processing industry increased at a slower rate than did national income. Because of the inherent weakness of gross output indices (primarily due to the inclusion of intermediate products), however, the achievements and problems related to the production of particular major products also will be considered in the ensuing paragraphs.

#### *A. Crop Output and Yields*

During the third FYP period, crop production was up by an average of only 1.9 percent, much lower than the reported 3.9 percent increase for the livestock sector. Crop output during the fourth FYP (1971-75) was 16 percent higher than during 1966-70, for an average annual increase of 3 percent. Hungary, achieved outstanding success in two major crops (wheat and corn), while the production of sugar beets and, especially more recently, of vegetables lagged behind expectations and domestic needs.

*Crop output averages for 1971-75 (1966-70=100)*

Crops:	Output during 1971-75
Wheat.....	143.4
Rye.....	77.6
Barley.....	96.1
Corn.....	147.3
Sugar beets.....	97.5
Potatoes.....	79.5
Fruits.....	113.7
Vegetables.....	103.1

Wheat is a major crop whose importance lies in the fact that it satisfies the nation's demand for bread (which is still a major staple in Hungary), it contributes to foreign exchange earnings, and it is the major source of cash income for many collective farms.<sup>4</sup> Since the 1960's, when the country was forced to import wheat to feed its population, major strides have been made in increasing production. Average output during 1971-75 was 43 percent higher than during 1966-70. Today, the application of advanced technology and high yields characterize Hungary's wheat production.

Wheat output in 1975 was lower than usual because of adverse weather conditions. During the rain-soaked harvest, field operations were delayed and in some areas harvesting combines could not even

<sup>4</sup> *Figgelo*, June 19, 1974

get on the fields. The major obstacle to further increases in wheat production, however, is the continued acute shortage of adequate drying and storage capacity.<sup>5</sup>

Impressive results have been reached also in *corn* production. In recent years, output and yields reached unprecedented levels because of adequate rain during the growing seasons, good weather during the harvests, and the continuing extension of industrial methods of production (now over 60 percent of the crop is produced under this method). Average output during 1971-75 was over 47 percent above the 1966-70 output level. In 1975 total corn output reached 7.1 million tons, and yields reached an average of 50.2 quintals per hectare. While there were increases in the yields of other grains such as rye and barley, their output did not reach the 1966-70 average during 1971-75 because of reduced acreage.

In the past, domestic production of sugar beets generally was sufficient to satisfy domestic sugar requirements and, occasionally, even to result in sugar exports. During the late 1960's, however, due to conflicting and controversial government decrees, there was a reduction in sugar beet acreage, reducing output to 1.9 million tons on about 74 thousand hectares in 1971. Since then, due to the slow expansion of the area under cultivation, production did not increase sufficiently to eliminate sugar imports, since, in the interim, because of higher incomes, domestic demand for sugar has increased. The sugar beet crop amounted to 4.1 million tons in 1975, harvested from 127 thousand hectares. Acreage was increased about 30 percent in order to eliminate or substantially reduce the need for sugar imports (imports that could be obtained only for hard currency). While acreage was higher, the sugar yield from the crop was poor because of inadequate processing facilities. Thus sugar imports have continued.

Hungary's most important oil seed crop is sunflower. About 80 percent of the sunflower crop is planted with high yielding Russian varieties; in recent years sunflower seed oil has been an important source of foreign exchange. Other oil seeds produced in Hungary include rapeseed, flax, and soybeans. Soybean production is still in a rather experimental stage, however, despite the development of a strain to suit local conditions. Due to the expected low profit potential, many producers have been reluctant to grow soybeans and produce highly profitable corn instead. The country can cover only about 20-25 percent of its oilseed meal requirements from domestic sources; the rest must be imported to satisfy the demand of its expanding livestock industry.

The production of vegetables during 1971-75 was only 3 percent higher than during 1966-70. Compared to the previous year, in 1976 acreage shrank from 120 thousand to 108 thousand hectares and output declined by 17 percent.<sup>6</sup> The problems of vegetable production are not new, since fulfillment of vegetable production plans fell short also during previous periods. The major cause of production problems has been not the weather but the reduction of material incentives to producers. The production costs of vegetable production increased both absolutely and as compared to the cost of producing other crops.

<sup>5</sup> For a discussion of storage problems, see Section IV below.

<sup>6</sup> For an elucidating discussion of current problems, see *Figyelo*, June 23, 1976.

As the cost ratios for vegetable production deteriorated; many producers rechannelled their resources into more profitable employments.

Agricultural labor is expensive and is often not available in sufficient quantity during peak demand periods. Mechanization—with the notable exception of the production of green peas—so far has increased only the cost of production but not its yields. Between 1970 and 1974 labor costs rose by 22.5 percent whereas the producer prices of potatoes and vegetables were up by only 8 percent and 11 percent, respectively. Even though producers can obtain machinery for vegetable production at a 70 percent state subsidy, production is still unprofitable. In some cases, such as at the Kossuth Cooperative in Tompa, mechanization meant losses. A 40 percent profit by the farm at tomato growing via labor intensive methods during 1970–71, changed to a substantial loss (on the area devoted to tomato growing) by 1976 because of the purchase and use of machinery.<sup>7</sup> According to some estimates, in 1975 and 1976 most farms were raising vegetables at a loss.<sup>8</sup>

### B. Livestock Production and Yields

The output of the livestock sector showed a rapid average annual rate of increase of 3.9 percent and 4 percent during 1966–70 and 1971–75, respectively. However, at least during the fourth FYP, performance was worse than reported because of large scale slaughtering of breeding stock of both cattle and hogs during 1974 and 1975. Poultry and egg production showed solid gains: poultry production during 1971–75 exceeded that of the previous five-year period by 33 percent; egg production, by 26 percent.

Cattle breeding and milk production are considered by many as the most backward branches of Hungarian agriculture.<sup>9</sup> Performance during the last few years has done little to alter this image. Cattle stocks are smaller than planned, the number of cows is fewer than a decade ago, and milk production as well as milk yield have stagnated over the years. The production, handling, and storage of rough fodder improved little over the last three decades.<sup>10</sup> Since 1960 over thirty government decrees have been promulgated in connection with cattle breeding; none of them enjoyed any lasting success, since they were unable to improve profitability. Indeed, cattle breeding and milk

<sup>7</sup> *Ibid.*

<sup>8</sup> *Ibid.*, September 22, 1976.

<sup>9</sup> *Nepszabadsag*, January 28, 1976.

<sup>10</sup> *Ibid.*

production have been basically unprofitable (except on small farms), with production costs rising faster than milk yields and revenues. While milk yields on the average were less than 2,400 liters per cow in 1975, great disparity is observable among the three basic types of producers: on collective farms the average yield is 2,300 liters; on state farms, 3,300; on small peasant farms, 5,000.<sup>11</sup> While during 1971-75 total milk output reached that of the previous five years, it was 14 percent less than planned (9.2 billion liters as opposed to the planned 10.5 billion), and milk yields per cow were 10 percent lower than planned.<sup>12</sup>

At the end of 1975 the total cattle population numbered 1.9 million, down 5 percent from the previous year. The number of cows declined by 4.6 percent in one year, down to 760 thousand. After two years of emphasis on milk production, in 1974 emphasis was shifted to meat production. This policy was continued in 1975 when the prevailing high prices of fodder and feed made milk production increasingly unprofitable.<sup>13</sup> The reduced profitability forced many producers to abandon milk production and market their cattle for meat. While this policy, therefore, increased meat output for 1975, it resulted in a drop in milk production. These developments came, moreover, at a time when the government continued its program of attempting to expand milk supplies, in part to cover the rising demand of the population for dairy products. Nor are the shortages of dairy products likely to be eliminated in the near future, even when the cow population regains its former size. The stagnation of milk yields can be reversed by means of cross breeding, but only after a period of time can widespread increases in yields be expected. In the interim, two forces will tend to exacerbate the prevailing shortages: first, increases, however small, in per capita real incomes in the years ahead will increase the demand for dairy products more than proportionately to the increases in income; second, the altered relative prices of meat and dairy products (following the July 1976 meat price increase) will result in increased demand for dairy products—even with unchanged incomes.

The production of hogs for slaughter increased by 7.5 percent in 1975 as compared to the previous year, exaggerating the significant apparent increase for 1971-75 over 1966-70. The reason for the increase was the abandonment of pig breeding and the slaughter of many sows by small scale producers, thus contributing to the subsequent absolute drop in hog production in 1976.

Small scale producers (users of household plots and owners of small private holdings) account for over 50 percent of total pork production in Hungary.<sup>14</sup> About half of this output is consumed by the breeders themselves; the other half is purchased by procurement agencies. In addition to the declining profitability of hog breeding in general—which reduced the output of collective farms also—small farmers were discouraged from hog production in at least two other ways. First, the procurement agencies inflicted losses on the producers by long delays in purchasing that necessitated the use of additional fodder; second, the local tax authorities were seeking additional taxes from

<sup>11</sup> *Magyar Hírlap*, April 18, 1976.

<sup>12</sup> *Pivýelo*, June 2, 1976.

<sup>13</sup> *Magyar Nemzet*, May 23, 1976.

<sup>14</sup> *Pivýelo*, August 4, 1976.

small scale producers, claiming that hog breeding entailed a 60 percent profit. Both policies resulted in discouraging hog raising. As a consequence, the hog population was 1.3 million head fewer in December 1975 than it had been a year previously, including a decrease of over 100 thousand in the number of sows.<sup>15</sup> As could be expected, the production of slaughter hogs fell in 1976. The substantial meat price increases in July of that year, however, can be expected to alleviate the existing shortages through expanding supplies by making hog production more profitable and through encouraging the use of substitutes in the population's diet.

#### IV. RESOURCE USE

Expanding agricultural production was accompanied by the substitution of increased machinery, fertilizer, and technology<sup>16</sup> for some of the land and labor used by the farms. There was a slight reduction in the land area used for crops and livestock, primarily because of forestation projects and various industrial, mining, transportation, and urban development projects. Agricultural employment fell to about one-fifth of the labor force. Further reductions are certain, primarily as a result of the young leaving agriculture. Moreover, manual laborers are difficult to attract or keep in agriculture because of the differences that still exist in wage rates and conditions of work between agricultural and nonagricultural employment. The young who do stay in agriculture prefer certain "fashionable" trades such as ornamental plant growing. Interest among the young in animal breeding, on the other hand, has been on the decline for years.<sup>17</sup> The main reason why labor shortage in the collectives has not become more acute is the spread of closed production systems and the associated expansion in the use of modern, Western machinery with labor replacing qualities.

On the basis of quantitative indicators, significant amounts of resources were devoted to agriculture during the last decade. The use of chemical fertilizers more than doubled since 1965 (to a respectable 270 kg. per hectare of agricultural land) and there was an expansion in irrigation capacity. The number of grain combines and trucks increased from 9 thousand and 7 thousand, respectively, to 14 thousand and 21 thousand, respectively, in ten years. Mechanical hauling power as a percentage of total hauling power increased during the last decade from about 75 percent to close to 100 percent. While the number of tractors fell, their capacity improved. Agricultural work has become much easier since the advent of the Raba-Steiger tractors that are manufactured through a U.S.-Hungarian cooperative agreement.

The appearance of the Raba-Steiger tractor has been a particularly bright spot in the recent history of Hungarian agricultural mechanization. With the advent of closed production systems in Hungary during the early 1970's, it became obvious that agriculture needed high-powered, efficient, multi-purpose machinery. Such machinery not being available in the Soviet bloc, the Hungarians turned toward

<sup>15</sup> *Nepszabadsag*, March 18, 1976.

<sup>16</sup> For a discussion of technological changes and the various closed production systems, see Section VII below.

<sup>17</sup> Comments by Minister of Agriculture and Food Pal Romany *I Elelmezési npar*, July, 1976, translated by JPRS (October 14, 1976).

Western markets. A few Steiger tractors were purchased in 1973 and assigned to the Babolna Agricultural Combine for testing.<sup>18</sup>

In 1974 the U.S.-made tractors were introduced on farms using the closed production system under the direction of Babolna. They achieved instant success and the acquisition of more such tractors was proposed. At the prompting of Babolna farm managers the Hungarian Wagon and Machine Factory in Győr bought a license and also entered into a cooperative agreement with Steiger for joint production of a Raba-Steiger 245 H.P. machine. According to the plans of the Ministry of Agriculture and Food, by 1980 there will be about 1,000 Raba-Steiger tractors operating on Hungarian farms.<sup>19</sup>

Certain problems in mechanization do exist, however, and mere quantitative indicators hide some important problems. Difficulties exist because many domestically made tractors are hopelessly obsolete,<sup>20</sup> because of the low capacity of some of the Soviet made combines, and because of the perennial scarcity of spare parts and delays and interruptions in machinery deliveries from the CMEA countries. For instance, the Soviet Union has often failed to deliver newly ordered machines on time, and German Democratic Republic and Czechoslovakia have frequently failed to supply the necessary spare parts.<sup>21</sup> Despite public statements by the leadership that small scale farms should be better supplied with machinery, the flow of machinery and spare parts to these farms has been poor for years. Shortages have existed in small tractors from Czechoslovakia, in inexpensive Italian garden sprayers, and even in garden tools such as spades. It seems that the Hungarian machine industry is given no incentive for producing for the small farmer. There is also a shortage of multi-purpose machinery to be used with the Raba-Steiger tractors.<sup>22</sup>

While the government has provided significant support to increase mechanization, resources have been underallocated to the establishment and expansion of storage and processing facilities, as in grains and sugar beets. Such capacities have often failed to keep pace with the growing production of crops. In the case of grains, there is a serious shortage of both drying and storage capacity. While total drying capacity approximates total requirements, much of the equipment is outmoded, its regional distribution is inconsistent with the location of production, and its misuse (e.g., excessively rapid drying) results in lower quality grains.<sup>23</sup> Modern grain storage capacity is only 2 million tons, about half of requirements.<sup>24</sup>

The production of sugar beets has also expanded more rapidly than has storage and processing capacity. Because of the slower expansion of processing capacity, the required factory processing period has increased to 150-160 days (instead of the optimal 80-90). The longer storage, in turn, has decreased the sugar content of the beets.<sup>25</sup> In recent years there has been also a shortage of cold storage

<sup>18</sup> *Nepszava*, September 27, 1975.

<sup>19</sup> *Figyelo*, September 17, 1975.

<sup>20</sup> Some domestically manufactured tractors are so obsolete that spare parts for them have to be made to order. Some of these tractors are expected still to be in use in 1977. See *Nepszabadsag*, July 23, 1976.

<sup>21</sup> *Magyar Nemzet*, June 18, 1974; *Magyar Hirlap*, November 16, 1975. To bring the spare parts supply problem under control, an airlift was organized in 1976, but its cost turned out to be almost prohibitive. See *Nepszabadsag*, July 1, 1976.

<sup>22</sup> *Magyar Hirlap*, October 28, 1975.

<sup>25</sup> Kovacs and Vancsa, *op. cit.*

space, hampering the expansion of frozen food exports to the West. Almost one-third of the machinery and equipment in that industry is obsolete and needs replacement.<sup>26</sup>

## V. DOMESTIC CONSUMPTION AND FOREIGN TRADE

The consumption and foreign trade of agricultural commodities are related through the regime's efforts to improve the population's diet. Over the years, the change in the importance of domestic consumption has been revealed by conscious choices, often resulting in reduced exports or increased imports of foodstuffs.

Consumption of high quality foods has increased substantially during the last ten years. For instance, the per capita consumption of meat and fish together increased by 32 percent; of eggs, by 44 percent. While 1975 and 1976 were characterized by shortages of milk and dairy products at existing prices, over the last ten years the consumption of dairy products (without butter) increased by 29 percent. As expected, as a result of increases in per capita incomes, per capita consumption of potatoes and flour (bread) declined absolutely.

In some years exports of foodstuffs were decreased or imports increased to ensure uninterrupted food supplies. For instance, starting at the end of 1974 and continuing through 1975 milk production fell. To avoid shortages at the existing prices, cheese exports and the production of powdered milk for animal feed were reduced. In 1976, expecting increased domestic demand, cheese exports were discontinued, powdered milk production was further reduced, and the country resorted to butter imports. Also in that year, vegetable and potato shortages were alleviated through imports.<sup>27</sup>

Agricultural products have not been unimportant in Hungary's foreign trade, and their importance is likely to increase as a result of the 15-year agricultural agreement signed with the U.S.S.R. in October 1975<sup>28</sup> and another barter agreement, signed in early 1976, whereby Hungary is to swap agricultural commodities for Soviet oil, cotton, timber, and cellulose.<sup>29</sup> To live up to these agreements, Hungary will undoubtedly have to increase its agricultural output, especially livestock breeding. As the responsibility for meeting the increased export commitments will fall mainly on the state and collective farm sectors, the position of small scale producers in meeting the domestic demand for food is not likely to fall.

Since 1965 Hungary has successfully eliminated its wheat imports and has become a net exporter of wheat. Slaughter cattle and pig exports have expanded, as has the export of corn, dressed poultry, pork, and eggs. While the 1974 EEC meat embargo reduced Hungary's lucrative beef exports to Western Europe, these exports were redirected to the U.S.S.R., also for hard currency.

Two major commodities—animal feed and sugar—have had to be imported, despite efforts to eliminate such imports.

Protein fodder is an essential ingredient in meat production. Domestic production of protein fodder satisfies only about two-thirds

<sup>26</sup> *Figyelo*, April 25, 1975.

<sup>27</sup> *Nepszava*, May 21, 1976.

<sup>28</sup> *Világgazdaság*, October 23, 1975; *Nepszabadság*, December 19, 1975.

<sup>29</sup> *Világgazdaság*, March 27, 1976.

of demand; the rest is imported, mainly from the West. Future increases in domestic fodder production are likely, however. Hungarian scientists have perfected a process that transforms nontoxic grasses and waste vegetables into edible protein. The process has been licensed worldwide under the Vepex trademark and made available for export. Several Western countries have bought licenses.<sup>30</sup>

Raw and processed agricultural products account for close to one-half of Hungary's exports to the West. Hungary is making great efforts to reverse its unfavorable Western trade balance by increasing agricultural exports. It seems, though, that its efforts are not likely to be very successful until its problems surrounding domestic livestock and vegetable production and processing are successfully tackled.

## VI. PRODUCTION PLANS THROUGH 1980

The fifth FYP<sup>31</sup> envisages a 3.2–3.4 percent average annual increase in the gross output of agriculture. Crop output is to increase at a 3.6–3.8 percent rate; livestock production, at 3 percent. The most important areas to be emphasized are cattle breeding, pig breeding and fattening, vegetable farming, and fruit farming. The food processing industry is to increase its output at an average annual rate of 5.2 percent, mainly as a result of several new investments and reconstruction projects.

Grain production is to increase to 14 million tons; grain exports, to 3 million tons. Central grain storage capacity is to be expanded to 2.7 million tons. Cereal production is to increase via increased yields. Plans also call for a "considerable" increase in fruit and vegetable production, as well as an increase in the area (by 40 thousand hectares) devoted to oilseed crops.

The law stipulates that meat and milk production are to be increased—the former by 12–13 percent, the latter by 14–15 percent over the 1971–75 average. The keeping of livestock on household and private garden plots is to be supported more intensively than in the past. Marketing channels are to be improved and the acquisition of sows and fodder supplies will be guaranteed to small scale producers.

The bulk of investment resources is to be allocated with the aim of increasing the level of mechanization and expansion of capacities via reconstruction projects. Export oriented or import replacing activities are to get major support. For instance, new meat processing plants will be built at Gyula, Baja, and Szekszard, a cold storage plant at Zalaegerszeg, and a vegetable oil plant at Martfu. Another meat processing plant, already started at Szeged, is slated for completion, and cold storage plants will be completed at Miskolc and Szekesfehervar. Plans have been finalized also for a new sugar beet processing facility at Hajdusag. These processing facilities will facilitate Hungary's compliance with the ten-year Soviet-Hungarian barter agreement (concluded in March, 1976) whereby Hungary is to exchange processed agricultural materials for Soviet raw materials.<sup>32</sup>

## VII. NEW FEATURES IN HUNGARIAN AGRICULTURE

## A. The NEM in Agriculture

The basic aim of the Hungarian reform was the sustained and balanced growth of national income by means of allowing a broader scope to a "guided" market. In agriculture as well as in the other sectors, instead of the former system of administrative control and binding operational instructions, the state was to confine itself to methods of indirect control (procurement prices, credits, subsidies), leaving specific production decisions to the producers. Such freedom on the part of producers, in turn, was conceived of as a necessary condition for the achievement of greater economic efficiency.

Introduction of the basic principles of the NEM into the agricultural sector<sup>33</sup> meant a significant alteration in the role and functioning of the existing collective farms. The first noteworthy change came in August, 1965, when interference by district councils in the planning process of collective farms was prohibited. Instead, the agricultural cooperatives were to prepare their plans on the basis of contractual agreements with state procurement agencies, the only compulsory target remaining the acreage to be sown with bread grains.<sup>34</sup> Concurrently, steps were taken to increase the cooperatives' bargaining power relative to that of the monopolistic state agencies; according to the law, contacts had to be based upon the principle of equality.<sup>35</sup> The basic reform blueprint itself was contained in the May, 1966, Central Committee resolution,<sup>36</sup> as approved and further expanded by the Ninth Party Congress later that year.<sup>37</sup> The appropriate laws pertaining to the agricultural producers' cooperatives were passed by the fall session of Parliament in 1967 and became effective on January 1, 1968.<sup>38</sup>

As part of the effort of placing the operations of collective farms on a more businesslike basis, procurement prices were selectively increased. The procurement price level had already been increased 9 percent in 1966 and another 8 percent in 1967.<sup>39</sup> Starting with 1966, collectives had to form depreciation funds for the replacement of buildings, machinery, and other assets. Just as state enterprises did, they also had to establish the usual development, sharing, and reserve funds. In spite of all this, however, even today agricultural producers are far from being financially independent. Due to the continuing low procurement prices—because of efforts to maintain both low domestic food prices and the competitiveness of agricultural products in foreign grade—an elaborate system of state subsidies has had to be maintained in agriculture. Subsidies are available for construction, machinery, breeding stock, adverse natural conditions, and even for the employment of qualified experts. In anticipation of greater financial independence, there was also a revaluation of agricultural assets. That

<sup>33</sup> In the following discussion, "agricultural reform" will pertain mainly to the reforms in the collective farm sector. In 1968 collective farms covered some 80 percent of the total agricultural area.

<sup>34</sup> *Keletmagyarorszag*, August 25, 1965. This requirement was eliminated subsequently.

<sup>35</sup> See Janos Keseru, "A gazdasagi mechanizmus reformjanak egyes kerdesei es a termelozovetkezetek," *Kozgazdasagi Szemle*, XIII (October, 1966), pp. 1149-1150.

<sup>36</sup> *Nepzabadasag*, May 29, 1966.

<sup>37</sup> *Ibid.*, December 4, 1966.

<sup>38</sup> See *Magyar Kozlony*, October 11, 1967. For enabling decrees by the minister of agriculture and food, see *Magyar Kozlony*, October 24, 1967. The following secondary sources provide an in-depth explanation of the reform in the agricultural sector: Miklos Villanyi, *Penz es hitelgazdalkodas a mezogazdasagban* (Budapest: Kozgazdasagi es Jogi Konyvkiado, 1968); and Laszlo Csate, *Jovedelem, koltsseg, ar a termelozovetkezetekben* (Budapest: Kozgazdasagi es Jogi Konyvkiado, 1967).

<sup>39</sup> *Nepzabadasag*, January 27, 1967.

portion of the collective farms' debts in excess of the value of their fixed assets was written off as of December 31, 1966. To help place all collectives on a more equal financial basis, a graduated land tax was introduced reflecting the differences in the relative productivities of different parcels.

The regulations effective January 1, 1968, attempted to provide greater production incentives, fuller resource (primarily labor) utilization, and greater competition in the production, processing, and sale of agricultural products. The methods used included the multi-channel distribution system, changes in the rules pertaining to the distribution of collective farm income, increased governmental emphasis on household plot and ancillary production activities, and the establishment of interest group representation for collective farms.

Under the old system, collective farms were compelled to sell their products to designated purchasing enterprises at specific procurement prices. The principle of equal rights, accompanied by the formation of the multi-channel distribution system, meant that with the exception of products specified as state monopoly (slaughter beef and hogs, bread grains, tobacco, etc.), farms were allowed to purchase their inputs from a variety of sources and to sell their produce to a variety of buyers. They were also allowed to transport their products to different parts of the country to take advantage of market opportunities. While an official distribution channel for fodder existed for the use of state and collective farms until 1969, small scale producers were allowed to purchase fodder on the free market only, frequently at twice the official price. In 1970 the state Grain Trust established a widespread distribution network in the villages, causing a more equal distribution of animal feeds.<sup>40</sup>

Prior to the reform, income distribution took place in accordance with the residual principle; the farm had to meet all its financial obligations toward the state and other claimants, and only then could members be paid. This system led to a mass emigration of able-bodied manpower from agriculture in search of superior alternatives in industry. The average age of collective farm membership rose to between 54 and 55 years,<sup>41</sup> with most members of the "weak" collectives being between 60 and 70 years old.<sup>42</sup> At the same time the farms were forced to hire able-bodied employees at the higher, competitive wage. The hired employees also enjoyed the superior social benefits already available to industrial workers.<sup>43</sup>

The reform specified that for members, work on the collective farm is not only a duty but also a right. Managements, therefore, were instructed to ensure steady employment for the members, in accordance with their skills. Further, the residual principle was abolished and members' incomes were thereafter determined on the basis of regular cash payments and year-end profit shares. The regular wage paid to members (one-twelfth of 80 percent of their expected share in net income) became a production cost taking priority over other commitments.<sup>44</sup> Contrary to the rules in the other sectors, the law did not stipulate a required ratio for the allocation of net income into

<sup>40</sup> *Magyar Hírlap*, October 13, 1970.

<sup>41</sup> *Nepszabadsag*, June 20, 1967.

<sup>42</sup> *Ibid.*, July 6, 1967.

<sup>43</sup> *Ibid.*, June 20, 1967.

<sup>44</sup> *Ibid.*, October 25, 1966.

the various funds. Any allocation consistent with the "socialist" system of income distribution was acceptable. The reform increased also the family allowances payable to collective farm members.<sup>45</sup>

Undoubtedly due to the importance in satisfying the population's demand for food and contributing to foreign exchange earnings, the reform reaffirmed the regime's official stand that the maintenance and support of private plots is not a temporary but a long-range principle of agrarian policy.<sup>46</sup> While there was no change in the authorized size of household plots (.28-.57 hectares), there was a change in eligibility. Before the reform, only members with independent households were eligible; after the reform, every member who fulfilled the minimum work requirement on the common farm became eligible for a private plot. The purchase of small machines for private plot cultivation became somewhat easier but is still not satisfactory.

Before the reform, some 50 percent of the collective farm membership was idle during the winter months.<sup>47</sup> To increase farm incomes and effect a fuller labor utilization in an economy characterized by a severe labor shortage on the macro level, farms were encouraged to expand their ancillary activities. While ancillary activities were not illegal before the reform, the various ministerial enabling decrees interpreted the general law in a markedly restrictive fashion. The NEM ended years of debate concerning the proper scope of the collectives' activity. They were encouraged to broaden their activities (processing, marketing, provision of services), the only proviso being that the main activity had to be agricultural and that nonagricultural production should not affect farm output adversely. While the scope of the authorized activities was later restricted,<sup>48</sup> most farms still engage in ancillary activities.

Since it was reasonable to expect more intense competition in the economic arena after 1968, the NEM enabled collective farms to obtain interest group representation. To enable them to better defend their economic interests vis-a-vis monopolistic state enterprises, forty-nine federations of cooperatives were formed on a regional basis. Such federations can examine the economic problems common to collective farms, make recommendations, and deal with state agencies on behalf of individual collective farms. Moreover, the first National Congress of Cooperatives in 1967 elected the National Council of Agricultural Cooperatives, an organization with the function of a national agency for interest protection.<sup>49</sup>

Lastly, the reform enabled the collective farms to acquire the land they were using through purchasing it from members and non-members.<sup>50</sup> At the time of large scale collectivization (1959-61), peasants retained nominal titles to their land and were paid rent by the collectives (subject to the residual principle). Before the reform it was at least legally possible for members upon withdrawal or expulsion to get back the same amount and quality of land they took into the collective. According to the new law, members could continue to retain title to their land or sell it to the collective, whereas non-members had to either join or sell their land to the collective for a

<sup>45</sup> *Magyar Nemzet*, May 17, 1968.

<sup>46</sup> *Nepszabadsag*, September 29, 1967.

<sup>47</sup> *Ibid.*, June 16, 1967.

<sup>48</sup> Ancillary activities that were distant from agricultural production were prohibited. See *Magyar Hirlap*, December 3, 1971.

<sup>50</sup> *Nepszabadsag*, December 4, 1966.

"fair compensation." While changes in ownership, strictly speaking, are not expected to alter output or productivity under the circumstances, the new land law is still significant because it ended even the legal possibility of the former owners' ever withdrawing land for their private use.

### *B. Horizontal and Vertical Integration*

Following the completion of large scale collectivization, the prevailing trend in the early 1960's was the reorganization of farms by the consolidation of economically weak units into viable, larger operations. From the peak of approximately 4,500 in 1961, the number of collective farms declined, and the area cultivated per farm increased. During the late 1960's, many members of the leadership on the local level argued that the horizontal amalgamation of farms should continue due to the (assumed) economies "inherent" in large scale production (improved management, increased technical efficiency, etc.). Mergers thus continued with the result that, by 1975, the number of collective farms dropped to 1,599 and the average area cultivated by farm increased to 3,500 hectares. The merger movement among state farms has been more moderate; nevertheless, by 1975, their number dropped to 151, with an average area of 6,000 hectares.

More recently it has been recognized by the top leadership that once sufficient size has been attained, further enlargement of size is bound to yield diseconomies; as could be expected, various problems, primarily in the coordination of activities and in "cooperative democracy," have begun to appear.<sup>51</sup> Certain farms obviously have become excessively large, and further amalgamations generally have been discouraged.

Since the completion of the large scale collectivization drive in 1961, the most noteworthy and significant new feature in Hungarian agriculture, besides the NEM, has been the appearance and expansion of closed production systems (cps).<sup>52</sup> Also known as industrialized production systems, the essence of the cps lies in the application of a "package" of inputs in order to achieve a sequential set of programmed tasks—the final, overall objective being the attainment of maximum yields and revenues at a minimum cost. Production systems entail the use of the most up-to-date machinery, pesticides, seeds, and technology, and the optimal coordination of all environmental, biological, and institutional forces in the framework of scientific management.

Production systems have legal structures equivalent to those of enterprises and can thus enter into contracts, own equipment, etc. They consist of a system manager (usually a leading state farm) and several partner farms, the relations between the manager and the farms being defined in a contract. The system manager has to possess the intellectual, material, technical, and organizational conditions necessary for the establishment and continual further development of the system. It is responsible for the procurement, maintenance, and repair of machinery; procurement of the other inputs; the adaptation of its methodology to the conditions of the partner farms; and

<sup>51</sup> *Ibid.*, May 23, 1975 and October 7, 1975.

<sup>52</sup> See *Magyar Hirlap*, June 30 and July 12, 1973; *Nepszabadsag*, July 13, 1973; Laszlo Bethlendi, "Iparszere termelési rendszerek a mezogazdaságban," *Közgazdasági Szemle*, XXI (May, 1974), pp. 536-573; and Erno Csizmadia, "Új vonások a hetvenes évek magyar mezogazdaságában," *Közgazdasági Szemle*, XXI (June, 1974), pp. 641-655.

conducting the research and analysis needed for the further development of the system. The partner farms must adhere to the technological instructions, provide skilled personnel, and acquire the needed machinery and other materials. The system manager's remuneration is a prearranged share of the incremental profit (in the four systems dealing with corn production, it is 5-20 percent).<sup>53</sup>

The criteria for the establishment of cps are specified by the Ministry of Agriculture and Food. The main criterion is that the incremental profit earned must exceed the incremental cost before the obsolescence of the acquired machinery. Since the appropriate machinery usually has to be imported from the West because of the low quality standards of the CMEA countries, costs and profits are stated also in hard currency. Other criteria include the financial conditions of the partners and availability of appropriate labor resources.<sup>54</sup>

Such cps have been introduced in both livestock and crop production. Their success in livestock production generally has been mixed, with the notable exception of poultry and egg production by the Babolna Agricultural Combine. With the help of U.S. technology and a cooperative agreement with a West German firm, in 1970 Babolna began to breed hybrid poultry and sell poultry and eggs on Western markets.<sup>55</sup> Today broiler and egg production at Babolna enjoys internationally high standards and a favorable international reputation and export markets. The raising and fattening of hogs via cps, on the other hand, has met only a qualified success. In one case, hogs were being fattened in dark, windowless buildings with inadequate ventilation and consequently suffered oxygen deprivation.<sup>56</sup> Elsewhere, unreliable fodder supplies by the Grain Trust and incompetent managers made large-scale operations impractical.<sup>57</sup>

In crop production the introduction of production systems has been very successful. Introduced experimentally on six thousand hectares for corn production by Babolna in 1970, acreage under the various cps has expanded rapidly.

<sup>56</sup> *Figyelo*, December 12, 1973.

<sup>57</sup> *Ibid.*, February 6, 1974.

In 1975 eighteen systems were operating in crop production (of which four were in corn) over an area in excess of 900 thousand hectares. Further expansion, however, is to be more gradual; according to the Ministry of Agriculture and Food, permits for the establishment of new systems are to be more carefully scrutinized due to the lack of the necessary prerequisites (skilled workers, efficient management, and adequate financial reserves) on many farms.<sup>58</sup> Judging from the speeches and articles of high party and government officials, the likely future trend in production systems is in the direction of vertical integration in which farms, processing plants, and marketing organizations participate.

The introduction of the NEM enabled agricultural producers to perform vertically integrated functions through the expansion of ancillary activities. By the end of 1968, 94 percent of all agricultural producers' cooperatives operated or shared in the operation of subsidiary enterprises.<sup>59</sup> Those farms that possessed insufficient financial resources for the establishment of ancillary activities were able to do so through the formation of "common undertakings." By 1974 over 500 associations existed, over half of which were legal entities.<sup>60</sup> Nevertheless, intersectoral cooperation (i.e., between collective farms and state enterprises) has been hindered by several factors.

The clash of sectoral interests, such as between sugar beet growers and processors, has hindered the efforts toward greater integration. (The growers' interest calls for late harvests so as to attain a higher yield, whereas the processors' interest dictates staggered deliveries to the plant so as to relieve the pressure on storage facilities and reduce the length of the processing cycle.) Additionally, when the decree governing vertical intersectoral cooperation was promulgated,<sup>61</sup> it had the effect of discouraging joint enterprises due to the requirement that the joint enterprise form virtually all the enterprise funds normally formed by state enterprises. Finally, the high concentration of the Hungarian food processing industry also has tended to retard vertical integration between collective farms and state enterprises. All firms within a given sector are controlled by a trust; these trusts have been unwilling to loosen their control over the firms sufficiently to encourage greater flexibility.

A recent tendency has been the formation of agricultural combines and agro-industrial associations. An agricultural combine is formed by the merger of large, previously independent, vertically integrated units (such as state farms already performing many ancillary activities) under one management. An example is the Agricultural Combine at Babolna. An agro-industrial association is an organization in which independent state enterprises and collective farms participate. They retain their independence but establish close cooperation in the achievement of some task by synchronizing development plans, concentrating their investments and fixed assets on particular activities, etc. Due to the very recent promulgation of the decrees governing their formation and scope of activities,<sup>62</sup> at present there are only a few agro-

<sup>58</sup> *Magyar Hírlap*, June 5, 1974.

<sup>60</sup> Csizmadia, *op. cit.*, p. 648.

<sup>61</sup> *Magyar Kozlöny*, August 7, 1970.

<sup>62</sup> *Ibid.*, June 19, 1976.

industrial associations operating in the country. An example is the Szigetkoz Agro-Industrial Association in Győr county, created by the association of one state farm, ten collective farms, and six state food processing enterprises. It controls 48 thousand hectares of land, and its main purpose is to expand the country's cattle breeding and vegetable production.<sup>63</sup>

The formation of agro-industrial associations is consistent with the proposition that economies of scale do not obtain to the same extent in all operations that constitute farming or agriculture-related production. The selective enlargement of scale, therefore, may open up additional possibilities for increasing efficiency. The main future direction now appears to be the establishment of such regionally organized quasi-industrial production systems of several producing units, vertically encompassing the production, processing, and marketing functions.

### C. The 1976 Changes

In 1975 actual budgetary subsidies exceeded greatly the amounts planned for agriculture, the budget assuming the burden of world market price changes. At the same time, both the members' personal incomes and the investment expenditures of collectives exceeded the aggregate planned magnitudes, contributing to the existing disequilibria in the consumer goods and investment markets. Changes in the regulators were not designed to alter the regime's basic agrarian policy; one major purpose of the 1976 changes in general was to increase the portion of net income accruing to the budget—and, consequently, to reduce the portion left with the enterprises. For the agricultural sector the planned yearly reduction amounts to the net transfer of an additional 2 billion forints to the treasury.<sup>64</sup> The major methods used to effect the income transfer are to be found in the price changes affecting agriculture and in various tax policies.<sup>65</sup>

In addition to income transfers, the planners wanted also to communicate to the producers the altered cost ratios that came into being on the world market during the last few years. In agriculture, pursuance of this policy meant that concurrently with raising procurement prices by various increments reflecting planned output preferences, input prices were also raised, prompting producers to substitute for costlier inputs whenever possible. During the last few years, increases in industrial producer prices were not passed on to agriculture but were absorbed by budgetary subsidies. As of January 1, 1976, prices of fuels, machinery, fertilizer, insecticides, herbicides, and protein fodder were raised.<sup>66</sup>

Changes in tax policy affected primarily the collective farms. The existing land tax remained, in essence, unchanged, except for a slight alteration in rates in favor of farms possessing lower quality land. Social insurance contributions were raised, as was the progressive rate of the tax on increments to member incomes. There was also a change in the tax rate applicable to ancillary production activities.

<sup>63</sup> *Kisalföld*, October 28, 1976.

<sup>64</sup> *Függetlenség*, October 20, 1976.

<sup>65</sup> See *Penzugyi Kozlony*, July 30, 1975. For a detailed discussion of the changes in the economic regulators pertaining to agriculture, see Decree 1030/1975 by The Council of Ministers, published in *Magyar Kozlony*, November 15, 1975.

<sup>66</sup> For the specific increases in input and procurement prices, see *Penzugyi Kozlony*, September 4, 1975.

Rates were reduced on activities closely related to agricultural production (e.g., processing) and raised on activities of an unrelated nature. The general income tax of cooperatives (based upon the total wage bill) was replaced by a progressive tax based upon per capita gross income (comprised of total wages plus profit).

The subsidy system was retained virtually intact, except for small changes in rates; e.g., for tractor purchases the rate was increased from 10 to 20 percent; for other machines, reduced from 47 to 40 percent. The maximum subsidy remains at 70 percent.

Assuming no significant offsetting policies, the changes in the regulators are bound to reduce the net income of the agricultural sector. It is not clear, however, whether they will elicit the desired changes in the structure of production. So far the input and procurement price changes have not altered the relative profitability of the crop and livestock sectors. Crop production, on the average, still yields a 26–28 percent profit, whereas the expected profit in livestock production is 0–0.5 percent. On the average, ancillary production results in a profit of 11–13 percent.<sup>67</sup> It is not surprising, therefore, that the planned expansion of livestock production by enterprises is at odds with the annual plan targets. Under these conditions, unless significant production incentives are introduced, meat supply problems will tend to be perpetuated. There is a wide difference also in the profitability of vegetable production and grain production. The new tax on gross income provides a further disincentive for the production of labor intensive products (e.g., vegetables) because labor costs comprise the dominant portion of the gross income of cooperatives. It remains to be seen whether the 1977 procurement price increases for vegetables will provide an adequate inducement for the expansion of vegetable production to eliminate the potential shortages.

### VIII. CONCLUSION

During the past decade significant efforts have been made to increase the output and efficiency of Hungarian agriculture. Provision of greater economic incentives within the framework of the NEM, increased mechanization, the more intensive application of artificial fertilizers, as well as the spread of closed production systems in crop production undoubtedly have contributed greatly to the recorded output gains. On the debit side, shortages of spare parts, high-quality machinery, manpower, protein fodder, and storage facilities, together with the pursuance of occasionally inappropriate or conflicting economic policies, have detracted from the otherwise noteworthy accomplishments. The tempo of further growth, therefore, is likely to be profoundly influenced by, inter alia, the type of direct economic incentives offered to producers in the form of procurement prices, subsidies, and input availabilities, the degree of exploitation of the opportunities existing in the foreign sector, and the nature of policy coordination and implementation by central and local administrative units.

## I. SUMMARY

The East European countries were informed by the USSR in the early 1970s that oil deliveries in 1976-80 would be held to the 1975 level. This presented the East Europeans with a dilemma as they rely heavily on increased Soviet oil deliveries to meet their growing energy needs. The East European regimes first responded by planning massive imports of Middle Eastern oil but the explosion in world oil prices subsequently forced them to gear down these plans. In order to fill part of this growing energy gap, the East Europeans then launched programs to accelerate development of domestic energy resources and

improve efficiency in fuel use. The burden was further eased when the U.S.S.R. relaxed its limits on oil deliveries somewhat to accommodate those East Europeans investing in Soviet resources development and those facing particularly serious economic difficulties.

Despite these adjustments, energy plans in 1976-80 are very taut with strains already appearing in 1976. If energy supplies fall short, the East Europeans probably will have to reduce economic growth goals. It is unlikely, however, that leaderships will cut back planned improvements in consumer living standards very much. The U.S.S.R. is unlikely to provide much more oil in 1976-80 unless political stability in Eastern Europe is at stake.

## II. INTRODUCTION

Since the early 1960s, Eastern Europe,<sup>1</sup> in an effort to rationalize production and speed economic growth, has been shifting from almost exclusive reliance on domestic coal for its energy supply to a more balanced pattern using increasing amounts of oil and natural gas. Because of the paucity of these energy resources in East European countries except Romania, however, the bulk of their oil and natural gas has been imported, mainly from the U.S.S.R. Soviet oil has been especially critical in the rapid expansion of East European chemical and petrochemical industries, in the mechanization of agriculture, and in the modernization of the transport and metallurgical sectors.

## III. CURRENT USE PATTERN

### A. Coal

Eastern Europe entered the 1970s as the only major industrialized area that still relied heavily on coal. In 1970, for example, coal supplied about 70 percent of primary energy consumption in Eastern Europe (see Table 1). The two largest economies—Poland and East Germany—depended on coal for over 80 percent of their energy supplies. Reserves of coal in Eastern Europe are quite large and represent about 150 years supply at current production rates (see Table 2). Except for Polish coal, however, most of these reserves are brown coal and lignite.

TABLE 1.—EASTERN EUROPE: COMPOSITION OF PRIMARY ENERGY SUPPLY, 1970

Source: "Handbook of Economic Statistics", 1976, Central Intelligence Agency, p. 78.

In the 1971-75 plan period, as the East Europeans moved to reduce the growth of coal usage, production grew only 1.6 percent annually. Most of the increase was attributable to a rise in hard coal output in Poland. Production fell in Bulgaria, East Germany, and Hungary and rose only slightly in Czechoslovakia as these countries deliberately downplayed the production of coal that was diminishing in quality and accessibility. A number of countries even closed less efficient mines. Because Poland exports almost one-quarter of its hard coal, consumption in Eastern Europe grew even slower than production, increasing by less than 1 percent annually.

Overall energy consumption grew by 4 percent annually during the same period (see Table 3).

<sup>3</sup> Estimated plans.

*B. Crude Oil*

Although the East Europeans succeeded in reducing coal's share of energy consumption during 1971-75, limited reserves prevented them from offsetting that decline with domestically produced crude oil and natural gas.<sup>2</sup> Crude oil reserves amount to only 196 million tons (1.4 billion barrels),<sup>3</sup> less than 0.3 percent of world oil reserves and only about twice the level of East European oil consumption in 1975<sup>4</sup> (see Table 4). Romania has over 80 percent of these reserves.

Sources: Statisticheski Yezhegodnik Stran-chlenov Soveta Economicheskoy Vzymopomoshchi, 1975, and East European Statistical Yearbooks.

Despite efforts to boost production sharply, East European crude oil production grew at an average annual rate of only 1.4 percent during 1971-75. Output totaled only about 17.5 million tons in 1975 and accounted for about 20 percent of consumption. About 84 percent of the area's crude oil output came from Romania. The more industrialized East European countries (East Germany, Czechoslovakia, and Poland) produce negligible amounts of crude oil. Despite strenuous Romanian efforts to boost production, the growth of its crude oil output has slowed since the mid-1960's, increasing only 1.7 percent annually during 1971-75. Output totaled 14.6 million tons in 1975. Hungary, the only other significant producer, has experienced even more difficulty in raising production; output increased only 0.7 percent annually during 1971-75.

*C. Natural Gas*

Eastern Europe was more successful in raising natural gas production in 1971-75, but gas reserves are small. Proved and probable reserves totaled 620 billion cubic meters in 1975, about 10 times 1975 consumption.<sup>5</sup> Romania accounts for about 40 percent of Eastern Europe's gas reserves and more than 60 percent of its gas production (see Table 5 for East European gas production and consumption).

<sup>3</sup> The same is true for hydroelectric power and nuclear energy. Most East European countries have limited hydroelectric power potential and nuclear energy will not become a significant factor until the 1980's.<sup>4</sup> All references to tons are metric tons.<sup>5</sup> Reserves amount to about an 11-year supply at 1975 extraction rates.<sup>6</sup> Reserves amount to about a 12-year supply at 1975 extraction rates.

Although gas output in Eastern Europe grew by 8 percent annually during 1971-75, it still was below the 12 percent recorded during the previous five-years. Output of 64 billion cubic meters in 1975, however, met 83 percent of the area's consumption needs. Growth in 1971-75 was spurred by new finds, especially in East Germany, Hungary and Poland.

#### D. Imports

The slow growth of coal production and the generally small amount of oil and gas reserves has forced the East Europeans to rely heavily on imports to meet most of their energy needs. During 1971-75, such imports grew 12 percent annually, nearly four times the growth rate of domestic energy production. By 1975, imports of energy accounted for about 17 percent of consumption, compared to slightly over 11 percent in 1970. Excluding Poland, with its coal, and Romania, with its oil and gas, imports of energy for the other four countries rose from 36 percent of consumption in 1970 to 56 percent in 1975.

The U.S.S.R. has supplied the overwhelming share of Eastern Europe's crude oil imports and virtually all of its natural gas and electricity imports. Excluding Poland and Romania, the energy dependence of the other four East European countries on the U.S.S.R. is extremely heavy. Between 1971-75, import increases from the Soviet Union comprised over nine-tenths of the growth in energy consumption of Bulgaria, East Germany, and Hungary and over one-half of Czechoslovakia's. Soviet oil deliveries total 271 million tons; by 1975, deliveries to the five importing countries reached 63 million tons (1.3 million barrels/day) and accounted for 86 percent of their total crude oil supply. Meanwhile, Soviet natural gas deliveries increased fourfold to 11.3 billion cubic meters and electricity deliveries doubled to 10 billion kilowatt hours. By 1975, the U.S.S.R. accounted for 13 percent and 25 percent, respectively of East European gas and primary electric power consumption.

Eastern Europe was in large part insulated from the dramatic explosion of world energy prices in 1973-74. Trading prices within the CEMA were scheduled to remain fixed until 1976 and only a small share of its total oil imports came from the Middle East. The Soviet crude oil price to Eastern Europe in 1974, for example, was under \$3.00 a barrel or about one-quarter of the world price. In January 1975, however, the Soviet Union more than doubled the prices of its oil,

natural gas, and coal to Eastern Europe (see Table 6). The cost of these imports jumped from 1.6 billion rubles (\$2.1 billion) in 1974 to 3.2 billion rubles (\$4.5 billion) in 1975.<sup>6</sup>

In addition to boosting oil prices, the U.S.S.R. also instituted a system of annual price adjustments based on a moving 5-year average of world prices. Consequently, the price of oil to Eastern Europe rose 8 percent in 1976 and 22.5 percent in 1977 to about \$9.10 a barrel.<sup>7</sup> These price changes resulted in a deterioration in East European terms of trade with the U.S.S.R. and forced them to divert goods from domestic and hard currency markets to the Soviet Union to pay for the higher priced Soviet goods.<sup>8</sup>

Perhaps of greater concern to the East Europeans is the Soviet attempt to limit oil exports to them in 1976-80 to 1975 levels. Because the increase in Soviet oil deliveries in 1971-75 accounted for 30 percent of the increase in all East European energy consumption, a leveling off of Soviet oil supplies would harm East European economic growth. The Soviets have since eased the limitations because of Eastern European willingness to undertake new investments in the U.S.S.R. and severe economic difficulties in some of them. Despite these adjustments, Soviet oil deliveries in 1980 still will be only an estimated 23 percent greater than in 1975; during 1971-74, deliveries rose 57 percent. Tables 7 and 8 list actual Soviet deliveries in 1971-75 and estimates for 1976-80.

Poland is the largest beneficiary of this Soviet largesse. According to the 1976-80 protocol, Poland was to receive only 50 million tons of crude oil and 6.5 million tons of oil products. The U.S.S.R. exported 58 million tons during 1971-75. Soviet concern about Polish economic problems, as well as Polish construction of an oil pipeline in the U.S.S.R., prompted Moscow to raise the delivery target to 75 million tons.<sup>9</sup> Because of payback from investment in Soviet projects in 1966-67, East Germany and Czechoslovakia will both receive about 20 million tons of oil by 1980 (compared to 15-16 million tons in 1975). Hungary also has been promised additional oil beyond the 1976-80 protocol in return for Hungarian oil equipment deliveries to the U.S.S.R.

Soviet efforts to reduce the growth of exports is attributable to production constraints in the U.S.S.R. In 1976-80, Soviet production is scheduled to increase 4.8 percent annually, compared with 6.8 percent in 1971-75. Even the present 1980 Soviet target of 640 million tons is expected to be underfulfilled by at least as much as 8 percent.<sup>10</sup>

East European imports of Soviet oil had been growing faster than Soviet oil production for some time. In 1965, such imports accounted for 9 percent of Soviet production; in 1975, they represented 13 percent. In restricting oil exports, the U.S.S.R. was attempting to keep Eastern Europe's share of Soviet production from rising further. If the

<sup>6</sup> Rubles are converted at the 1974 rate of \$1.32 per ruble and the 1975 rate of \$1.39 per ruble. Further numbers in the text will be denoted in dollars, converted from rubles at official rates of exchange.

<sup>7</sup> CEMA foreign trade prices in 1975 were based on a 3-year world average, i.e., 1972-74. The 5-year price bases began in 1976 with prices based on 1971-75 world levels; 1977 CEMA prices are based on 1972-76 world price levels and so on. In the case of oil, the 1977 price still is substantially less than the direct sale price of \$12.09 charged for Saudi Arabian benchmark crude in March 1977.

<sup>8</sup> East European prices to the U.S.S.R. also have been rising but to a lesser degree. It is estimated that Eastern Europe experienced a 10-percent terms of trade decline with the U.S.S.R. in 1975 alone with even higher declines for Hungary, East Germany, and Czechoslovakia.

<sup>1</sup> Estimated from various sources including a number of interpolations based on actual 1971-75 deliveries and announcements of 1976-80 projected deliveries.

<sup>2</sup> Components may not add to totals because of rounding.

U.S.S.R. achieves its 1980 target, the East European share will remain at about the 13 percent level of 1975; any production shortfall would raise the share correspondingly.<sup>11</sup>

The Soviet Union has for some time pressed the East Europeans to seek additional oil supplies elsewhere to make up for the slower growth in Soviet deliveries. The U.S.S.R. also has advised the East Europeans to increase their participation in Soviet oil and raw material development projects if they expected increased Soviet deliveries. In addition, Soviet officials have told the East Europeans to develop their own resources more fully, to increase the use of coal (especially for electric power plants), and to accelerate the use of modern energy-saving technological processes.

#### IV. SEARCH FOR INCREASED SUPPLIES

##### *A. Turn to the Middle East*

After being told early in the 1970s of the Soviet intent to limit 1976-80 oil exports, the East Europeans turned to the Middle East for relatively cheap oil to fill the gap. Hungarian Price Board Chief Csikos-Nagy explained pre-1973 Hungarian policy in a statement applicable to most of the rest of Eastern Europe:

[Prior to the 1973-74 price increases for oil]—on the world market, one could obtain some 10,000 calories with \$17 of oil purchases while 7,000 calories of coal cost \$23. In these circumstances it seemed reasonable for Hungary not to make the conversion of its energy structure from coal to hydrocarbons dependent upon the degree to which the Soviet Union was able to raise oil and natural gas exports

<sup>11</sup> Assuming, of course, that the U.S.S.R. meets its commitments to Eastern Europe.

to Hungary. Even the endeavor toward replacing the extremely uneconomically mined domestic coal through oil imports from nonsocialist countries seemed justified.<sup>12</sup>

Thus, while East European imports of Soviet oil were scheduled to drop from an annual growth of 10.6 percent in 1971-75 to only 3 percent in 1976-80,<sup>13</sup> the planned increase in imports from the Middle East probably was expected to completely make up the difference.

Based on this expectation, Poland launched a refinery building program designed to more than double capacity to 28 million metric tons by 1980. Such construction was initiated even though Soviet deliveries were not scheduled to increase above the 10 million tons annually provided in 1971-75. Hungary and Czechoslovakia joined with Yugoslavia and Kuwait to construct the pan-Adriatic oil pipeline across Yugoslavia. The pipeline originally was expected to provide Yugoslavia with 24 million tons of Middle Eastern oil annually by 1980 and Hungary and Czechoslovakia with 5 million tons each. With large purchases planned by the other countries, crude oil imports from the Middle East were slated to skyrocket from 6.5 million tons in 1975 to 41 million tons in 1980.

The quadrupling of Middle East oil prices in 1973-74 dealt a serious blow to these expectations. Several countries cut back import plans immediately. Bulgarian imports of Middle Eastern crude dwindled from 2.1 million tons in 1973 to 400,000 tons in 1975; Hungary reportedly is sharply cutting its imports to about 500,000 tons in 1977.

The greatest impact, however, has been on East European import plans during 1976-80. The five importing East European countries were forced to reduced planned imports of crude oil from the Middle East by two-thirds, to an estimated 13 million tons (see Table 9).<sup>14</sup> At current prices, the 41 million tons would have cost \$3.5 billion in 1980, compared with about \$600 million actually spent in 1975. This would put an intolerable financial burden on Eastern Europe. Soaring prices for raw materials and oil and recession in their de-

TABLE 9.—EASTERN EUROPE: CRUDE OIL IMPORTS FROM THE MIDDLE EAST

Hungary.....	1.5	6	3
Poland.....	2.4	18	4
Total.....	6.5	41	13

<sup>1</sup> Data are estimated.

<sup>2</sup> Revised plans are based mainly on announced changes in refinery capacity for 1980.

<sup>3</sup> Note.—Romania, which does not import any oil from the U.S.S.R., also imports oil from the Middle East. Romania purchased 5,000,000 tons in 1975 and is planning to increase these imports by 1980.

<sup>12</sup> Bela Csikos-Nagy, "The Raw Material Crises of the Capitalist World and the Economic Policy of Hungary," *Marketing in Hungary*, 1975, No. 1, p. 7.

<sup>13</sup> The 3 percent growth rate assumes no increase over 1975 deliveries and stems from the fact that deliveries were lower in 1971-74 than in 1975. Subsequent relaxation of the Soviet oil limit, raises the 1976-80 growth rate of Soviet deliveries to 6.2 percent.

<sup>14</sup> If Romania is included, planned imports from the Middle East total 24 million tons by 1980 (24 percent of total oil imports) compared with 12 million tons in 1975 (16 percent of total oil imports).

veloped Western markets already have led to record deficits and mounting debts. Moreover, OPEC's emphasis on hard currency sales and plans to limit oil production have made it difficult for the East Europeans to obtain new barter agreements and, in some cases, to maintain old agreements.<sup>15</sup>

Poland, with the most grandiose plans, also is retrenching the most. Planned refinery capacity is being cut back to accommodate crude oil imports of 20 million tons, compared with earlier plans of 28 million tons (present capacity is 15-16 million tons). Construction of new refineries at Czechowice and Poznan and the second stage of the Gdansk refinery—all scheduled for completion by 1980—have been postponed until 1981-85. The only refinery expected to come on stream in the next five years will be a 3-million ton facility at Blachownia Slaska. The existing refinery at Gdansk also will be expanded.

The Poles had little choice. In an attempt to correct a huge trade imbalance with the West, Poland has planned no growth in imports from the West during 1976-80. Imports of 18 million tons of oil in 1980<sup>16</sup> would have cost at least \$1.6 billion and the share of crude oil in total imports from the West would rise from 3 percent in 1975 to 24 percent in 1980. Instead, with the scaled-down plans and additional oil promised by the U.S.S.R., the Poles now plan to purchase only an estimated 4 million tons from the Middle East in 1980. Similar cutbacks have been made by the other East European countries. Hungary and Czechoslovakia for example, have trimmed planned oil imports from OPEC well below the oil supply anticipated from the pan-Adriatic pipeline.<sup>17</sup>

While the rest of Eastern Europe is slashing planned oil imports from the Middle East, Romania plans a huge expansion of such imports.<sup>17a</sup> In 1975 Romania was still a small net exporter of oil. With virtually no increases scheduled for domestic production of oil and natural gas during 1976-80 and dim prospects for purchasing Soviet oil, Romanian plans imply imports of an estimated 11 million tons of Middle Eastern oil in 1980 to meet their ambitious industrial growth targets. Continuation of present oil products sales—an important hard currency source—would raise imports to 17 million tons by 1980 and cost about \$1.5 billion. It is likely that import plans will have to be reduced to 9-10 million tons.

To achieve its planned goals, Romania would have to begin immediately to build additional refinery capacity to boost overall capacity from its present level of 24 million tons to 35 million tons. Romania has been negotiating for several years with Kuwait for the construction of an 8-million ton refinery at Constanta but the status of an agreement still is unclear. Even if new facilities were to be available by 1980, Romania still would need a large and quickly

<sup>15</sup> The East Europeans were able to arrange a number of agreements to exchange goods and services for OPEC oil but pay no hard currency. The East Europeans received an estimated one-half of their 1974 Middle Eastern oil imports on barter. The share under barter is believed to have declined dramatically since then.

<sup>16</sup> Eighteen million tons represents a ceiling. The Poles may have hoped to obtain more Soviet oil and thereby be able to lower imports from the Middle East.

<sup>17</sup> The pan-Adriatic pipeline may still be utilized, however, as the Friendship pipeline from the Soviet Union is already at its capacity of 50 million tons annually. The U.S.S.R. may find it cheaper to deliver OPEC oil to Eastern Europe on Soviet account through the pipeline rather than using more expensive barge or rail transport.

<sup>17a</sup> Romanian estimates were made prior to the March earthquake. While the full extent of the damage is still unknown, it is likely to affect these estimates.

exploitable oil discovery in the Black Sea or oil on easy terms from oil producing countries to be able to afford the additional oil. Its current hard currency debt of \$3.2 billion will not make the task any easier.

### *B. Development of Domestic Resources*

All the East European countries are stepping up investment to explore for oil, to develop existing energy resources, to reopen and modernize coal mines, and to recruit more miners with better housing and other benefits. Nevertheless, the growth of new energy production in 1976-80 is expected to increase at only 2.6 percent annually, a slight drop from the previous five-year growth rate. The low rate will prevail because output of oil in Romania and natural gas in Romania, East Germany, and Hungary will grow only negligibly.

Oil production in 1976-80 will increase at an average annual rate of only slightly more than 1 percent. Romania and Hungary, are not likely to expand current production significantly because their reserves are declining. The Hungarians originally had planned to hold production at the 1975 level of 2 million tons through 1980 but now have boosted planned production 7.5 percent. The Romanians have not changed their plans to increase production 6 percent to 15.5 million tons by 1980 (half the 1971-75 growth rate) but even this modest target will require extensive use of secondary recovery methods to eke out additional oil from existing fields.

The only hopes for a major discovery rest on offshore exploration. Poland and East Germany formed a joint organization with the Soviet Union in November 1975 to search for oil and natural gas in the Baltic Sea. Romania's first drilling platform began operating in the Black Sea in the second half of 1976; Bulgaria will begin Black Sea test drilling in 1979. Romania also is seeking cooperative ventures where Romanian assistance in offshore exploration and drilling will be repaid in oil. Although some of these efforts (especially Black Sea exploration by Romania) may yield results, it is unlikely that production would be significant before the 1980s.

Production of natural gas also will grow by only some 1 percent annually. Romania is holding output at the 1975 level to husband rapidly diminishing reserves. East Germany and Poland both fell far short of 1975 output targets as newly discovered fields proved disappointing. Poland may register a small gain in 1976-80 but East Germany probably will be unable to maintain the 1975 output level. Hungary expects output to peak at about 6 billion cubic meters in 1977 and remain at that level through 1980.

Nuclear energy output also will have little impact before 1980, except for Bulgaria. The addition of two 440 MW units will double Bulgarian nuclear capacity and enable nuclear energy to provide 20 percent of total electricity production by 1980. East Germany plans to put three 440 MW reactors on line by 1980, raising nuclear production's share of total electricity production to 8 percent. Less than 5 percent of electricity output in Czechoslovakia will be produced by nuclear energy by the end of the current plan period. Construction delays probably will prevent Hungary from bringing its first nuclear reactor on stream before 1981 (one year late); Romania and Poland will not have reactors operational before 1982.

With other energy sources scarce, Eastern Europe is returning to increasing domestic output of coal. Coal production plans call for a 3 percent annual growth in 1976-80, compared to the 1.7 annual gain achieved in 1971-75. One factor in the rather small increase relative to 1971-75 is that Poland, the major East European coal producer, already was pushing higher coal output in the early 1970s to obtain additional hard currency.<sup>18</sup> Moreover, brown coal production programs by Poland, Czechoslovakia, and Hungary are not expected to yield significant results until the early 1980s.

Poland, Romania, and Bulgaria plan greater boosts in coal production than the other countries. Poland has raised its earlier 1980 goal of 200 million tons of hard coal to 210 million tons, compared with the 172 million tons produced in 1975. Brown coal production of 40 million tons in 1975 will be boosted to 120 million tons by 1990, in large part through the development of the one-billion ton reserves of the Belchatow field. The Belchatow mine, Poland's largest energy investment during 1976-80, will produce 1 million tons of brown coal by 1980 and 40 million tons by 1985.

Bulgaria and Romania are making extensive use of open-cast mines in their planned increases in coal production of 40 percent and 90 percent, respectively. Bulgaria also will construct the largest underground brown coal mine in the Balkans. Romania's program, which is the most ambitious and the most difficult, already appears to be in trouble, lignite production in 1976 fell 5 percent below the 1975 level.

Although East Germany, Czechoslovakia, and Hungary have boosted earlier coal production plans, they still will be unable to achieve much growth. East Germany and Czechoslovakia face declining quality and accessibility in their brown coal production. Czechoslovakia estimates that the overburden for one ton of coal will increase from 2.6 cubic meters in 1970 to more than 3 cubic meters in 1980. Hungary, which initially had decided to allow production to decline 7 percent by 1980,<sup>19</sup> now is planning to maintain the 1975 production level until 1980. Brown coal mines being developed at Markushegy, Nagyegyhaza, and Many will enable production to grow 50 percent but not until after 1980.

### *C. Investment in Soviet Projects*

East European investment in Soviet resource development to be repaid in energy sources is not new, but there has been a dramatic increase in the size and number of such projects. The East Europeans are providing equipment, manpower, technical assistance and, in some cases, hard currency, in return for guaranteed future deliveries.

During the late 1950s and early 1960s, there was a spate of credit extensions against future materials deliveries within CEMA; most of these were small, typically bilateral, and mainly designed to increase the capacity of already functioning enterprises. The first large credit was extended in 1966 when Czechoslovakia agreed to supply \$550 million in machinery, equipment, and large diameter steel pipes during 1966-74 in return for 60 million metric tons of Soviet oil in

<sup>18</sup> Poland is the world's second largest coal exporter. In 1975, coal accounted for 33 percent of Poland's hard currency revenues.

<sup>19</sup> Bela Csikos-Nagy, *ibid.*

1971-80.<sup>20</sup> Payback of Soviet oil was to be at a fixed price. The volume was to increase steadily during the repayment period, reaching 5 million metric tons in 1975<sup>21</sup> and probably 10 million metric tons by 1980 (about half of Soviet deliveries for that year). East Germany signed a similar agreement in 1967 although the exact amount and terms of the credit are not known.

After being informed by the U.S.S.R. in the early 1970s that further increases in Soviet deliveries of energy and raw materials were contingent upon participation in joint investment projects, the East Europeans subsequently agreed to invest in a number of huge multilateral projects. Most are located in the U.S.S.R., including the Orenburg gas pipeline, Ust-Ilim cellulose paper plant, and the Kiyembay Asbestos Mining Combine.<sup>22</sup> The cost of these projects is expected to total about \$8.6 billion during 1976-80 alone, with the East Europeans contributing about \$4.5 billion. Labor participation costs may raise the total East European contribution to well over \$5 billion.

The largest project—and the most important to the East Europeans—is the \$5 billion Orenburg natural gas pipeline. The 1,700-mile, 56-inch diameter pipeline is to run from Orenburg in the southern Ural Mountains to Uzhgorod on the U.S.S.R.-Czechoslovakia border. Each East European country, except Romania,<sup>23</sup> agreed to build a separate section of pipeline with its own labor, equipment, and technical services at a total estimated cost of \$2 billion. Construction started in 1975 and is scheduled to be completed in late 1978.

The Orenburg agreement called for each East European country to make above-plan deliveries to the U.S.S.R. on credit during 1975-1978. By 1980, gas exports as payback will represent half of Soviet natural gas exports to Eastern Europe and account for about 20 percent of total East European gas consumption. In 1980-99, the U.S.S.R. is to provide 15.5 billion cubic meters of natural gas annually. Each participating country will receive 2.8 billion cubic meters annually. Romania will receive only 1.5 billion cubic meters annually.

In addition to huge multilateral deals, several East European countries also have signed bilateral agreements with the U.S.S.R. for additional energy supplies. Czechoslovakia agreed in 1975 to build a pipeline to West Germany in return for an extra 1 billion cubic meters of natural gas in 1980-99.<sup>24</sup> Poland will receive an additional 1 million tons of oil annually in 1977-80 for building a crude oil pipeline from Belorussia to Lithuania.

In most, if not all, of the joint investment agreements, the Soviet Union has made sure that the payback price is not specified but will be set at the time of delivery.<sup>25</sup> Thus, the U.S.S.R. is avoiding being locked into a low price over a long period, as it was in the 1966-67 oil agreements with Czechoslovakia and East Germany. One Soviet estimate is that that East European outlays in the U.S.S.R. will cover

<sup>20</sup> *Izvestiya*, 19 August 1969. The payback period later was extended to 1984.

<sup>21</sup> *Ekonomicheskaya Gazeta*, #19, May 1970, p. 20.

<sup>22</sup> Several projects are outside the USSR, however, including the expansion of nickel production in Cuba and the developments of a copper deposit in Mongolia.

<sup>23</sup> Romania is only providing a gas desulfurization plant, pipe, and equipment.

<sup>24</sup> The scheduled 28 billion cubic meter capacity of the Orenburg line will permit the U.S.S.R. to make sizable exports to Western Europe after satisfying the 15.5 billion cubic meter obligation to Eastern Europe.

<sup>25</sup> See, for example, *Den'gi i Kredit*, December 1974, p. 80.

only 40–50 percent of the cost of guaranteed deliveries.<sup>26</sup> The estimate can only be rough, as the actual prices paid by the East Europeans will depend on CEMA prices at the time of payback.

Despite its enthusiasm for joint investment projects, the U.S.S.R. must be disappointed with the early Orenburg results. The major types of assistance that Eastern Europe provides are hard currency equipment purchases and labor skilled in pipeline construction. Yet each country already has reduced its commitment because of shortages of both resources. East Germany will build only half of its section. Hungary and Czechoslovakia will build compressor stations but lay no pipe; Bulgaria has cut its commitment substantially. Only Poland will build an entire section but one (the section originally assigned to Hungary) that is closer to home.<sup>27</sup> All countries still must meet the financing requirements on their sections, but, except for Poland, much of the pipeline construction will be done by the Soviets.

The East Europeans, already suffering from large hard currency debts with the developed West, have had to restrict their hard currency purchases for Soviet projects. CEMA's International Investment Bank (IIB) borrowed hard currency for the Orenburg project and then provided these funds to the U.S.S.R., which has made purchases for the entire project. The East Europeans, however, owe the IIB for their share of Soviet hard currency purchases and, according to IIB rules, must repay in hard currency at world market rates of interest.<sup>28</sup> Several East European countries now are so heavily burdened with other hard currency debts that the IIB or the U.S.S.R. may have to ease their repayment demands.

Even the delivery of East European machinery and equipment on credit for Soviet projects is of little assistance to the U.S.S.R. because nearly all the East Europeans are running sizable trade deficits with the U.S.S.R. Instead of present deliveries against future payback, the U.S.S.R. is merely obtaining surpluses in non-convertible currency. The only advantage accruing to the Soviet Union is that it is able to specify the equipment and products it wants in return for its energy and raw materials. Indeed, the U.S.S.R. has implicitly recognized this by paying back "in many cases . . . the goods and services given before the project is completed."<sup>29</sup>

### D. Efficiency

The East European countries also are stressing greater efficiency in the use of energy. Thus, East German plans call for a 5 percent annual reduction of fuel consumption in industry while Romania and Czechoslovakia are planning cuts of 4 percent and 2–2.5 percent, respectively.<sup>30</sup> These savings targets are substantially higher than those of the previous five year plan. The other countries have released less data but also have indicated higher savings goals than in the past.

<sup>26</sup> V. Karpich, "Production Cooperation among CEMA Member Countries—Basis for the Progressive Development of their Trade," *Vushna Turgoviya*, No. 9, 1976, pp. 9–12.

<sup>27</sup> *Nepazabadsag*, 15 June 1975, p. 4.

<sup>28</sup> One effect of the channeling of East European hard currency borrowing and purchases through the IIB and the U.S.S.R. is a reduced understanding by Western bankers of the total East European hard currency position.

<sup>29</sup> M. Loshakov and A. Pomyenko, "Soviet Trade with European Socialist Countries," *Foreign Trade*, No. 12, 1976, p. 11.

<sup>30</sup> The East Europeans apparently measure savings in industry by energy consumed but not embodied in products. For example, the energy expended in refining crude oil would be included but not the oil that was converted to oil products.

The Romanians have published more detailed information than most other countries about their savings program. Fuel consumption per unit of output in industrial branches is to fall 11.5 percent in the chemical industry to 26 percent in the machine building industry (see Table 10). A large part of these savings (6.7 million tons of standard fuel) will come from recovery and use of waste heat from smokestacks, radiation, and cooling waters and metals in production processes. Romania also plans major gains in efficiency through the installation of large 330 MW capacity generating units in power plants with 2,000–2,500 MW capability. One-fifth of the new additions to power capacity will be thermal conversion units which will provide heat as well as electricity to factories and urban areas. Major changes also are planned by shifting to low energy intensive products and more efficient machinery. As in the other East European countries, all enterprises are subject to a comprehensive code of energy guidelines and norms.

There undoubtedly is opportunity for significant improvement in efficiency. As a result of still heavy reliance on coal and obsolescent machinery, East European efficiency lags behind West European levels. For example, Poland uses 1.9 kg of conventional fuel for \$1 of GNP, compared with 1.36 kg for the U.K., 1.0 for West Germany, and 0.7 for France.<sup>31</sup>

Moreover, the Poles admit that there are wide variations in efficiency between recently purchased Western machinery and older equipment. The electric power used in producing one ton of similar steel pipe by Polish enterprises, for example, ranges between 85 kilowatt hours and 479 kilowatt hours.<sup>32</sup> In another measure—the consumption of fuel per kilowatt hour—, Eastern Europe does somewhat better, when compared to Western Europe (see Table 11).

<sup>32</sup> For a comprehensive treatment of East European inefficiencies, see Edwin M. Snell, "Economic Efficiency in Eastern Europe," *Economic Developments in Countries of Eastern Europe, 1970*, pp. 240-296.

Savings of the magnitudes forecast in most East European plans will be difficult to achieve. Much of previous East European reductions in fuel consumption have resulted from conversion of plants and processes from coal to oil and gas. While such conversion will continue, its rate will be much slower. Because of growing oil and gas restrictions, some plants especially power plants, will be reconverted to coal. Moreover, power plants using coal will be operated at a maximum while those using oil will operate at a minimum. Because replacing a large portion of capital stock is costly, it will have to be done gradually. In Romania, for example, the 1976-80 plan to add over 60 percent to existing power plant capacity already has been cut back.

#### V. 1976-80 PLANS

Despite the obvious energy impediments, most East European countries still have set 1976-80 growth goals for national income and industrial production close to the performance of the previous plan (see Table 12). Moreover, planners project about the same growth rates for energy consumption as that achieved during 1971-75. Energy requirements have been increased, in part, to fuel the major expansion planned for the machine building and chemical industries—both heavy energy users. The anticipated growth of machine building production is due largely to the near-doubling of machinery exports to the U.S.S.R.<sup>33</sup> These exports are necessary to meet commitments for Soviet projects and to cover the higher prices charged for Soviet raw materials.

Rapid growth of the chemical industries is viewed by the East Europeans as more critical—"chemicalization" of their economies is considered the key to modernization, to increased efficiency, and to continued economic growth. They also see development of petrochemicals, especially plastics and synthetic fibers, as an opportunity to reduce hard currency imports and, in the case of Czechoslovakia, East Germany, and Romania, to increase hard currency exports. Czechoslovakia, for example, is planning to export larger amounts of chemical products to hard currency markets and to replace hard currency imports of cotton, wool, and leather with their own production of plastics.

Although Soviet oil sale restrictions and high cost Middle Eastern oil pose difficulties, earlier energy trends will continue during 1976-80.

<sup>33</sup> Mihoshakov, A. Pollyenko "Soviet Trade with the European Socialist Countries: Results and Prospects," *Foreign Trade*, No. 12, 1976, pp. 7, 9.

Energy imports will still grow faster than domestic production of energy and will rise to about 25 percent of energy consumption by 1980. Domestic energy production will grow more slowly, despite East European efforts to stimulate its growth.

During 1976-80, the Soviet Union still will be Eastern Europe's chief source of energy, supplying 75 percent of their crude oil imports (86 percent excluding Romania) and virtually all of their natural gas and electricity imports. Soviet supplies of natural gas to Eastern Europe will almost triple, although most of the increase will occur in 1979-80. Nevertheless, the rate of growth of Soviet deliveries of energy is declining despite the U.S.S.R.'s willingness to increase exports of oil and gas. The East Europeans are attempting to adjust to these lower levels by a) stepping up domestic production; b) increasing imports from the Middle East; c) improving industrial efficiency; and d) slowing overall growth slightly.

The East Europeans admit that their energy plans are demanding; some evidence of strains already appeared in 1976. Brownouts and power curtailments to industry have become more common. Czechoslovakia rationed electricity to both consumers and industry, and Poland rationed coal for home heating. The growth of Bulgaria's chemical industry fell far short of targets partly because of a pinch in oil supplies. Romanian lignite production declined 5 percent from the previous year, despite a huge planned increase, forcing it to expand production of their shrinking gas reserves. Romania's plan to reduce gas use in 1977-78 by enough to offset the overuse in 1976 signals a further pinch in energy supplies ahead.

If available energy supplies fall seriously short of plan, the East Europeans probably will be forced to reduce economic growth goals. It is unlikely that they will be willing to reduce planned improvements in consumer welfare very much—most consumers already are being asked to sacrifice and the memory of events in Poland in 1976 is still fresh. Without significant—and unexpected—improvement in trade balances with the West, it will be difficult for the East Europeans to increase oil purchases from the Middle East. And short of situations where the U.S.S.R. fears political stability is at stake, the Soviet Union is unlikely to provide much more oil in 1976-80.

Eastern Europe's energy situation may become even bleaker after 1980 because Soviet oil production is expected to peak or even decline by 1985. Any decline in Soviet oil deliveries would be critical for Eastern Europe's economic growth. Investments in nuclear energy and brown coal production will not bear significant fruit before the 1980s.

Premier Kosygin has proposed that the East European's invest in the construction in the U.S.S.R. of high volume petrochemical plants thus enabling the East Europeans to buy petrochemicals from the U.S.S.R. and reduce their oil requirements.<sup>34</sup> Eastern Europe could then specialize in the production of low tonnage, high technology products. The East Europeans, however, are certain to resist these proposals as increases in petrochemical production are central to their growth plans and hard currency export goals. Nonetheless, if Soviet crude oil becomes less accessible they may be forced to give serious consideration to the Soviet proposal.

## I. INTRODUCTION

Like other small industrialized countries, those of Eastern Europe have found it very difficult to independently produce on an economic scale such highly complex products as motor vehicles. Indeed, even the attempt by the Council of Mutual Economic Assistance (CEMA) to take advantage of the economies of specialization by assigning major product lines to member countries has not proven to be a viable alternative. As a result, in addition to intra-CEMA cooperation, the East Europeans have adopted bilateral arrangements with Western companies for product development and production technology. Moreover, the present pattern of development suggests that even if East European countries substantially expand cooperation among themselves, they will continue to depend on Western firms for the foreseeable future.

Although several East European countries have invested heavily in Western licenses, process technology and machinery to create or expand automotive production, the total capacity of the region is not large by world standards. Production of a million vehicles in 1975 can be compared to output of more than 800,000 in Spain alone. Moreover, few of the vehicles being produced are competitive in world markets.

The U.S.S.R. is not able to assist the East European countries with modern product design, manufacturing engineering services, or production equipment. Neither is it a ready source of common auto

motive accessories. For these items, the East Europeans mainly supplement regionally available supplies by importing from the West. However, the Soviet Union has provided an expanded market in recent years for automotive components made in Eastern Europe, thus assisting the producers in that region to reach economical scales of output.

This paper discusses the strategies developed by the East European countries in providing for their automotive transportation needs. It begins in Section II with a look at the condition of the auto industry in the area at the time when Communist regimes were established. Section III provides a description of the industries as they have developed since then. Section IV indicates that although Eastern Europe is dependent on the West for automotive technology, a substantial trade in vehicles and components takes place among themselves as they capitalize on extensive international specialization.

In Section V we discuss national policies on the production and use of motor transport, which have evolved substantially over the years, particularly with respect to private ownership of passenger cars. Finally, in Section VI there is an analysis of the basic economic problems in establishing automotive industries in small countries with command economies and of the measures taken to solve them.

## II. HISTORICAL PERSPECTIVE

In the late 1940s, following the end of the Second World War, only Czechoslovakia was able to produce motor vehicles in substantial numbers. Yugoslavia's production of a few hundred Praga trucks before 1950 was made possible by the supply of parts from the parent Czechoslovak firm.

In Hungary a desultory effort was made to reestablish the production of two models of German trucks made under license before World War II, but the effort was abandoned by 1949. Instead Hungary obtained a license to produce the Austrian 3½-ton Steyr-Daimler-Puch diesel-powered truck.<sup>1</sup> The major components of these trucks were also incorporated in Ikarus buses, a newly organized production activity which has become more successful in Hungary than truck production.

Reestablishment of motor vehicle production in East Germany, source of about a third of the total automotive output of prewar Germany, was held up until 1949 because the U.S.S.R. first dismantled and carried off most of the existing production machinery, and then organized the residual production facilities into Soviet companies to maintain, repair and make parts for Soviet military vehicles. When the East German motor vehicle industry finally was established, in 1949, it was only with substantial imports of production equipment and parts from West Germany and Czechoslovakia.

Poland began production of an indigenously designed 3½-ton truck, the Star-20, in 1948 in a remodeled German armaments factory. By 1951 the Poles were assembling the Soviet passenger car Pobeda (renamed *Warszawa*) at Zeran, and by 1952 the Soviet 2½-ton truck, GAZ-51, at Lublin. Both plants received their initial equipment from the U.S.S.R.

<sup>1</sup> The term, 3½-ton truck, indicates that the truck can carry 3½ tons of cargo.

Attempts at motor vehicle production were unsuccessful in Romania until the assembly of the Soviet ZIL-150 truck was undertaken at Orasul Stalin in early 1954 using Soviet technical assistance and parts. In 1957 the assembly of Soviet GAZ-69 jeeps was undertaken. Bulgaria did not attempt motor vehicle production until 1967 when an assembly plant for Soviet GAZ-53 trucks was established.

Yugoslavia assembled vehicles only from imported parts before World War II and had little indigenous capability. Today its industry is fairly well developed but suffers somewhat from a proliferation of West European models assembled from both imported and domestic components.

As the individual national industries developed during the 1950s it became evident that none was large enough to be efficient. There was considerable duplication, offering opportunities for economies through international specialization. The program of international cooperation devised by CEMA in 1959 proposed a division of responsibility for component parts of vehicles in addition to assigning the production of types and models to certain countries.

Most of the East European countries have strongly resisted loss of their rights to continue to produce whatever types of motor vehicles they choose. Nevertheless, some cooperation and coproduction has taken place since 1959, in most cases because cooperation was clearly an advantageous national course and not because CEMA ordained it. These cooperative arrangements are primarily bilateral, and coincidence with overall CEMA strategy is fortuitous.

The initial tendency toward dependence on the Soviet motor vehicle industry for parts and technology has been replaced over time by programs of coproduction with the U.S.S.R. Poland no longer produces or assembles Soviet models, and Romania's trucks have evolved into indigenous designs. Only Bulgaria still assembles Soviet light trucks and passenger cars from complete kits imported from the U.S.S.R., and sends some truck parts to the U.S.S.R. in repayment. The U.S.S.R. has been the major source of imported vehicles for Bulgaria.

Today, the countries whose motor vehicle industries are relatively new (Poland, Bulgaria, Hungary, Romania, and Yugoslavia) are engaged in cooperative and technological assistance programs with Skoda of Czechoslovakia or with one or more Western firms. East Germany still depends entirely on its own technology, but that suffers from a lack of modernization.

### III. NATIONAL CAPABILITIES

Eastern Europe produced about 1 million motor vehicles in 1975, of which more than three-quarters were passenger cars.<sup>2</sup> This volume of output was only 25 percent above that of Spain, one-half of the Soviet Union's, and 60 percent of France's. The following tabulation shows production in Eastern Europe in 1975 by major category of vehicle and producing country:

<sup>2</sup> See Table 1 for motor vehicle production in the USSR and Eastern Europe, selected years, 1950-1975. See Table 2 for motor vehicle registrations in Eastern Europe, beginning 1975. See Table 3 for characteristics of motor vehicles in production in Eastern Europe in 1975.

[In thousands]

France.....	2,952	347	3,299

Note: Data for Czechoslovakia, Poland, U.S.S.R., and Yugoslavia are from officially published statistical handbooks for those countries. Data for East Germany, Bulgaria, Hungary, and Romania are estimated from fragmentary published information for 1975 and statistics of previous years.

Although the scale of production is increasing it remains very small by world standards. Each of the larger producing countries has one major plant with a capacity of 100,000 to 150,000 cars a year and one or more smaller assembly plants. The truck facilities are even more diffused. The larger producing countries have several truck plants that produce 5,000 to 16,000 units a year. Bus manufacture is concentrated in Hungary and Poland (see Figure 1 for a map locating the principal automotive plants).<sup>3</sup>

#### A. Czechoslovakia

Of all the East European countries only Czechoslovakia has demonstrated the capability to carry out a viable indigenous and evolutionary program for the development of new models of trucks and passenger cars. The Czechoslovak industry dates from 1897, in the days of automotive pioneering, and it emerged relatively intact from ravages of the Second World War. Moreover, because it historically has enjoyed a good export market, it has had a high priority claim on national economic resources since the end of the War—a priority not initially given to the automotive industries of the other East European countries. As a result, the Czechoslovak industry has nearly kept pace with the advancing state-of-the-art in the West.

Although it was foreseen by the CEMA plan of 1959 that Czechoslovak technology would be a major factor in the development of the automotive industries of the other East European countries, only the exchange with Poland and Bulgaria of major components for Škoda trucks and buses materialized. Even so, the Polish heavy truck program, which was originally based on Skoda technology, has shifted to principal reliance on British, Swedish, and Austrian technology.

Czechoslovakia produces trucks of indigenous design in a rather large assortment of sizes and types (carrying capacities from 1½ to

<sup>3</sup> In the U.S., the average capacity of a car producing plant is 230,000; 65,000 for a truck plant.

14 tons) needed by a modern economy. Tatra trucks of 12- to 14-ton size, produced at Koprivnice, are in high demand in Eastern Europe and the U.S.S.R., and the annual capacity for manufacturing them is being expanded from roughly 7,500 to 15,000 during the 1976-1980 period. Much of the equipment is being imported from the West.

Plants at Liberec and Mníchovo Hradiste produce about 7,000 10-ton Skoda trucks a year, about half of which are exported. The Liberec plant, under a joint production agreement, also supplies components for the assembly of trucks at Bulgaria's Madara plant at Shumen. Production of the 10-ton Skoda Madara is about 2,000 a year. The Prague plant manufactures 5-ton heavy Praga trucks with Tatra engines in several versions at the rate of 5,000 a year for domestic uses and export. The Avia plant at Letnany manufactures light service trucks (1.5 to 3-tons) under license from Renault (Saviem) of France. The plant began assembly in 1968 using imported parts and now produces at about half the planned rate of 12,000 trucks a year, although new construction will raise output in the 1976-1980 period.

Czechoslovakia also produces about 2,000 Skoda buses a year for both urban and interurban transport. Chassis are made at Liberec, some for shipment to Poland, Bulgaria, and a number of developing countries which build their own bus bodies. A new line of Skoda, buses in various models has been produced at the Karosa Bus Plant at Vysoke Myto since 1970 for domestic use and for export.

Passenger car production in Czechoslovakia consists principally of the Skoda four passenger subcompact with rear engine and rear drive. Although it generally receives high marks in Western markets as a well made modern vehicle, the difficulty of obtaining parts and service in a timely fashion has resulted in a heavy price discount compared to the models of its Western competitors.

The Tatra firm, although best known for its heavy duty trucks, also turns out about two thousand high quality compact (6 passenger) cars annually. These are purchased for official use by Communist Party and other elites in Eastern Europe and the U.S.S.R. and are exported to Western countries. The design was originated by the famous Tatra designer, Hans Ledwinka, and is generally believed to have influenced Dr. Ferdinand Porsche's designs for the Volkswagen.

Prague is pushing ahead with plans to bring the industry up to world standard and to put into production a new line of cars for export. The government is spending heavily to renovate the Mlada Boleslav plant, the principal car producer, and to build a new assembly plant at Bratislava in Slovakia. Capacity of the plants will be 200,000 and 100,000 cars a year, respectively. The Bratislava plant was started in 1974 and on completion will assemble cars from components supplied from Mlada Boleslav, although it will make some body parts. Much of the equipment for the new facilities is being purchased in the West.

### *B. East Germany*

East Germany makes light and medium trucks and small passenger cars. The trucks, which are sold domestically or exported to other East European countries, are based on pre-World War II designs and have no market in advanced Western countries. The passenger cars

have two-stroke cycle engines of early vintage DKW (Deutsche Kraftwagen Werk) type which has been abandoned by all West European producers and will soon be discontinued in Poland as well. The lubricating oil for these engines is poured into the fuel tank, making it impossible for the engine to achieve West European emission standards. As a result, exports of these cars to Western Europe as hard currency earners will ultimately end. Consequently, East Germany is under some pressure to introduce a four-stroke cycle engine.

The East Germans negotiated with the Czechoslovaks for several years for a coproduction program that would provide East Germany with a Czechoslovak four-stroke cycle engine and in return, provide Czechoslovakia with East German transmissions. It was foreseen that such a division of labor would allow passenger car production in each country to go up to the 300,000 per year mark, generally considered in Eastern Europe to be the minimum economic scale of output. Moreover, substantial economies would come from producing major components in a volume of about 600,000 per year.

However, in late 1975 negotiations ended, apparently because of disagreement on the size of the common engine. In addition, there are probably other factors, such as a Czechoslovak preference for a rear engine rear drive design, while the East Germans favor front wheel drive. The latter is now preferred by many Western producers because it offers superior packaging of passengers and baggage. Moreover East Germany may wish a cooperative program with a Western firm to assure access to a continuing supply of modern product design and production technology. East Germany's continuing delay to modernize its obsolescent product and increase productive capacity probably also reflects difficulties in mobilizing hard currency to pay for modern Western production equipment and other technical assistance.

The larger of the two passenger car models, the Wartburg, is produced at Eisenach in the old BMW plant, at a rate of nearly 40,000 per year. The smaller Trabant is produced at Zwickau in the old Audi plant at a rate of about 100,000 per year. Although outmoded by Western standards, both sell well within Eastern Europe.

Production in East Germany's small truck industry has leveled off at roughly 35,000 units a year, although earlier plans called for a somewhat higher output. The industry is consolidating production by phasing out some models and specializing in three types, the 5-ton W-50, made at Ludwigsfelde, the 2½-ton Robur, made at Zittau, and the Barkas delivery van, made at Hainichen and Karl-Marx-Stadt. East Germany carries on a broad exchange of trucks with other Communist countries and is updating its transport fleet by buying Western made heavy truck-tractors from Daimler-Benz, Volvo, and FIAT.

Buses are no longer made in East Germany. In 1973 the industry phased out its small bus production and began to build chassis for bus plants in Hungary.

### *C. Hungary*

Hungary may have the economically most viable automotive industry in Eastern Europe. After attempting to establish truck and bus production based on pre-WWII components under license from Steyr-

Daimler-Puch of Austria, Hungary has narrowed its industry into two major specialities: (a) modern heavy components for trucks and buses, principally diesel engines and rear axles built under license from MAN of West Germany, and (b) modern heavy trucks and buses incorporating these components.

Hungary has three principal motor vehicle manufacturing facilities. These are the Raba-Mavag plant at Győr which produces diesel engines and rear axles under the MAN license, and assembles MAN heavy trucks using some imported MAN components; the Ikarus Bus Plant near Budapest which makes bus bodies; and the Csepel truck plant at Budapest which produces trucks and bus chassis under Steyr license, assembles all-wheel-drive trucks, and manufactures such major components as power steering gears and the gear box end of torque converter transmissions for trucks and buses.

Ikarus enjoys a good reputation for the design and production of large modern buses, both city and interurban. It exports buses in large numbers (about 90 percent of output) to both Communist and Free World countries, with the USSR taking the lion's share. Production reached close to 10,000 in 1975 and is scheduled to rise to 13,000 in 1980.

The Raba-Mavag plant in cooperation with MAN of West Germany builds heavy duty trucks and truck-tractors in a number of 2- and 3-axle variants at the rate of about 1,500 a year. Many of the MAN diesel engines and axles produced in the Raba plant are incorporated into Ikarus buses. Raba also ships rear axles to Soviet bus plants and in return, Ikarus receives Soviet automatic transmissions, power assisted steering gears, shock absorbers, and front axles for buses. Hungary receives transmission parts, bearings, shock absorbers and other parts for Ikarus buses from Czechoslovakia and Yugoslavia. East Germany supplies bus seats.

Hungary plans to discontinue the medium weight (5-6 ton) truck produced under Steyr license at Csepel and confine that plant's activity to high volume output of major components (transmissions, power steering gears, axles) for heavy trucks and buses for the export market in Eastern Europe and the USSR, and chassis for Ikarus buses. In addition, the Csepel plant has initiated production of a civilian jeep, the Swedish Laplander, under a joint venture with Volvo. The new firm—Hungary's first venture in joint ownership, with Sweden holding 48%—will build about 1,200 jeeps a year. Volvo will supply the engines and steering gear and Csepel the frames and bodies.

By avoiding the production of passenger cars, Hungary has greatly simplified its product assortment both in vehicles and components, thus permitting the industry to consolidate its resources and to produce high quality products. Success in this endeavor led to the co-production agreement with the Steiger tractor company, a U.S. firm, and may lead to a contract to supply heavy truck axles to the International Harvester Company. By 1980, nearly 30 percent of its exports of heavy vehicle components may go to hard currency areas.

Passenger cars are imported from both Eastern and Western Europe, and the currencies to pay for them are earned by exporting small component parts, such as car radios and wiper motors. The acceptability of these products is not based on public perceptions of worth or style, as is true of complete passenger cars, but on Hungary's ability to produce them to the user's specifications at attractive prices.

*D. Poland*

Unlike Hungary, Poland seems intent on establishing an integrated automotive industry with a complete assortment of product for all transportation needs. The Polish catalog of motor vehicles for local sale or export includes light, medium and heavy trucks, buses, and compact, subcompact and mini-compact passenger cars. With the exception of the medium weight Starachowice trucks, the vehicles and their components are produced under foreign licenses. The domestic burden of general industrial support for Poland's auto industry is considerably lightened by coproduction arrangements with foreign licensors.

In the past decade Poland has expanded its automotive industry nearly fourfold and has become the largest motor vehicle producer in Eastern Europe, surpassing the traditionally big producers, Czechoslovakia and East Germany. Poland's passenger car industry, is based almost wholly on FIAT licenses; over 85 percent of the 173,200 cars made in 1975 were FIATs. The major plant at Zeran near Warsaw builds FIAT 125 sedans, most of which are exported, and a new facility at Bielsko Biala in Silesia in 1975 started turning out the smaller FIAT 126 for the domestic market. At Zeran, the FIAT has completely replaced Poland's outmoded Warszawa which was based on a Soviet design. Warszawa chassis are still made for use in delivery vans. The Syrena, Poland's compact car, made at Zeran since 1957, has been redesigned and is produced at the small car plant at Bielsko Biala.

Poland has a substantial coproduction program with Yugoslavia which is made possible because both countries produce passenger cars under FIAT license, and, by exchanging parts, both achieve major economies of scale. Parts are received from Hungary for the Polski FIAT-126P and paid for by exporting the finished product to Hungary. Moreover, Poland is a major supplier of FIAT components to the Soviet VAZ plant at Tol'yatti.

Poland is also using Western assistance to upgrade its truck and bus industries. Many trucks, including the 4- and 6-ton Starachowice and 8- to 11-ton Jelcz, are outfitted with diesel engines of UK design. Poland builds the Leyland diesel engine under UK license and imports Perkins diesel engines from the UK. In 1975, Poland was licensed by Massey-Ferguson to produce Perkins engines. Technology from Austria's Steyr-Daimler-Puch firm is used for production of components (axles and chassis) for Jelcz trucks and steering and suspension mechanisms for Sanok buses. In 1974 Warsaw signed agreements with two Swedish firms that will provide technical assistance in exchange for components: Volvo will assist in building truck tractors at Starachowice and the Kockums firm will aid the building of dump trucks at Poland's Fadroma plant at Wroclaw. Poland is specializing in production of light service trucks, Żuk and Nysa, for the export market.

To strengthen its bus building capability, Warsaw in 1972 signed a joint production agreement with Berliet of France to make buses at the Jelcz plant at Wroclaw. At the capacity of 5,000 buses a year, the plant will be one of Europe's largest builders of urban, intercity, and tourist buses. Berliet is supplying technical assistance, equipment, and some of the components, and in return will receive finished buses and certain components.

Poland would like to diversify its product assortment further by introducing a line of light trucks and vans based on licenses and technical assistance from a Western firm but is presently having difficulty finding the necessary hard currency. Such a product ought to have a good market in Eastern Europe where consumer services are receiving increased attention, and existing production of such vehicles is still quite small.

### *E. Romania*

Bucharest is determined to build a strong and independent industry that is internationally competitive, with a view to selling its products in hard currency markets. Most of Romania's trade in automotive goods at present is with other Communist countries, to compensate for CEMA-produced industrial materials. Despite this reality, the government is standing firm against pressures for CEMA integration that would impinge on its pursuit of national goals for the industry.

In order to afford to import more Western technology, the government is studying the possibility of joint ventures with Western firms as a means of obtaining both the process technology and the capital funds for new automotive plants. Bucharest has approached Western firms, including several in the U.S., concerning joint production of small cars, heavy and light trucks, diesel engines, and various components.

Romania has four main assembly plants. The Dacia car plant at Pitesti produces 40,000 Renault cars a year with some assistance from France. Under a 1966 agreement, Renault supplied half of the components for assembly of the small sedans and received payment in transmissions. Presently Romania makes 80 percent of the components for Dacia cars and delivers 35,000 transmissions a year to Renault. Half of the Dacias are exported to other Communist countries, but Romania is testing the cars' competitiveness in hard currency markets in the hope of expanding exports to the West.

Romania's largest truck plant, located at Brasov, makes about 36,000 medium cargo trucks a year of the Bucegi model, derived from the Soviet ZIL design. Production of the obsolete Carpati 3-ton truck was discontinued around 1970. About half of the Brasov trucks are exported, many of them to China. Brasov also produces (a) 8- to 10-ton heavy diesel Roman trucks, under a 1971 cooperative agreement with MAN of West Germany, (b) MAN diesel engines and Saviem diesels (under Renault license), and (c) axles for MAN at the rate of 2,000 or more a year. Because Hungary also builds MAN components, Romania augments its domestic production by importing some varieties of engines from Hungary.

At Bucharest the industry turns out 4,000 buses a year on Brasov chassis for domestic and other CEMA markets. Jeep utility vehicles are made at Chimpulung at the rate of 8,000 to 10,000 a year, some of which are marketed in the West.

Romania has aspirations to produce large off-highway dump trucks in 25, 50, and 100 ton sizes but does not have the capability to develop and manufacture the necessary heavy diesel engines, power shift transmissions, axles or electric wheels. A few trucks have been produced in the 17-ton payload size using the 215 horsepower MAN engine.

*F. Bulgaria*

Bulgaria does not have an integrated auto industry but is developing production capacity and experience by making parts for export to the other Communist countries. In exchange for knocked-down Soviet GAZ-53 trucks, which are assembled at Shumen, Bulgaria exports component parts to the U.S.S.R. for the ZIL-130 truck. Bulgaria has contracts to supply the U.S.S.R. with power steering gears for the Kama truck, rear axles for other trucks, electrical equipment for VAZ passenger cars (Tol'yatti plant), such as batteries, generators, starters, regulators, and coils. Perkins (UK) engines have been made under license at Varna since about 1967.

Bulgaria also assembles Skoda Madara 8- and 10-ton trucks under license at Shumen, using Czechoslovak parts, and is committed to establish production of rear axles for Skoda trucks in repayment for imported parts. Production is expected to develop to the point where the Shumen plant may supply all of Skoda's rear axles and import only engines and transmissions from Skoda. An agreement with the West German firm Kässbohrer will allow Bulgaria to produce the Setra bus on the Madara truck chassis.

Bulgaria assembles Soviet Moskvich and VAZ passenger cars at Lovech from knocked down kits. During the last ten years, FIAT and Renault passenger cars have been assembled in Bulgaria in small numbers, but this activity has ended. In 1975 Bulgaria announced an agreement with Volvo on technology and trade including production sharing, but the lack of subsequent information suggests the proposed agreement was not implemented. Although Bulgaria signed a new protocol with Renault in June 1976, apparently it also has not been implemented.

Bulgaria is the leading producer of electric lift trucks in the Communist World and exports them to hard currency areas in substantial numbers. Bulgaria also has a substantial production capacity for lead-acid storage batteries, and exports them to all the Communist countries, including 300,000 a year to the USSR for the VAZ passenger cars.

Its comparative advantage in lift trucks has permitted Sofia to make a deal with Daimler-Benz to exchange lift truck technology for heavy Mercedes truck-tractors. Through a subsidiary, Daimler-Benz participates with Bulgaria's Balkankar Plant and Irion, a West German lift truck manufacturer, in a new company in Stuttgart to build Balkankar's three wheeled electric lift truck for sale in the West. Bulgaria uses the heavy Mercedes truck-tractors to haul freight trailers on its international routes.

*G. Yugoslavia*

The motor vehicle industry of Yugoslavia is characterized by a strong market orientation and substantial participation of Western firms, including equity holdings in Yugoslav plants. Four firms turn out passenger cars and five firms are engaged in assembling trucks and buses or producing components for them. With the exception of Zastava production at Kragujevac, Serbia, the manufacture of cars and commercial vehicles in Yugoslavia depends on the use of many imported components.

The industry is dominated by the Crvena Zastava Plant, which with its associated supplier plants comprises Yugoslavia's only integrated motor vehicle production enterprise and produces 80 percent of national automotive product. This firm was established in 1954 with FIAT technical assistance, and some FIAT equity ownership. Yugoslav production of components for FIAT cars has greatly increased over the years, and although coproduction of vehicles and exchange of parts still goes on between FIAT Turin and Crvena Zastava, the Yugoslav firm is substantially free of dependence on outside parts suppliers.

Crvena Zastava has cooperative production programs with a number of firms that also are engaged in producing FIAT products, including the Polski FIAT plants and the Soviet Tol'yatti plant.

The distribution of production among Yugoslav firms in 1975 is presented in the following tabulation.

Plant	City	Model	Output
<b>PASSENGER CARS</b>			
Total passenger cars.....			183,182

Crvena Zastava, based in Serbia, wants the other three passenger car firms, Cimos, IMV, and TAS, that assemble cars from imported parts, brought into a national corporation under Crvena Zastava's control so that passenger car production can be centrally planned. Regional factionalism, revealed in the public debate on this issue, and other considerations have held up the consolidation.

#### IV. TRADE PATTERNS

As shown in Tables 4 and 5, the U.S.S.R. is by far Eastern Europe's largest trading partner in automotive products, although the East European countries exchange their vehicles among themselves and most of them sell automotive products in the West to earn foreign

exchange. In 1975, Eastern Europe imported Soviet cars, trucks, buses, and parts valued at nearly 600 million rubles and supplied the U.S.S.R. with automotive products worth two-thirds that amount. The Soviet FIAT (VAZ-2101) is the principal East European import and Ikarus buses and automotive parts and components are the principal exports to the U.S.S.R. Trade totals for 1975 were as follows:

	Units			Million rubles	
	Cars	Trucks	Buses	Parts	Total
Imports from the U.S.S.R. ....	215,000	18,000	448	166	581
Exports to the U.S.S.R. ....	0	5,000	9,597	180	407

The VAZ-2101, known abroad as the Lada, is particularly popular in Eastern Europe because it offers the Western design and engineering features, so desired in Communist countries, without the need to spend hard currency. The U.S.S.R. thus has rapidly increased its share of the car markets in Eastern Europe since 1970 and is presently supplying about a third as many cars as the domestic plants are producing.

Eastern Europe has largely offset the rapid rise in imported Soviet passenger cars by a tripling since 1965 of exports of automotive products to the U.S.S.R., mainly in the form of parts for the VAZ-2101. The U.S.S.R. received in 1975 some 180 million rubles worth of parts and components for cars, trucks, and buses and over 225 million rubles of complete vehicles—mainly large city and intercity buses made in Hungary, and trucks from Czechoslovakia and Poland.

Czechoslovakia, East Germany, and Poland lead the other East European countries in the total export of cars; Hungary and Poland are the major exporters of buses; and East Germany, Czechoslovakia, and Poland of trucks. The countries supply each other with large numbers of parts and subassemblies under long-term bilateral trade agreements. Poland and Yugoslavia in particular have extensive cooperative programs for producing cars of FIAT design and during 1976-1980 will exchange components worth \$230 million.

Exports to the West come principally from Czechoslovakia, Poland, and Yugoslavia, each of which exports between 20,000 and 40,000 vehicles a year. Cars that are based on Western design and engineering enjoy moderate acceptance while those designed indigenously are less attractive to Western buyers.

## V. NATIONAL POLICY ON DEVELOPMENT OF THE INDUSTRY

During the initial stages of the post-WWII development of the motor vehicle industries of Eastern Europe, priority was given to producing medium sized stake and platform trucks with cargo capacities ranging from 2½ to 4 tons. This class and size of truck provides a useful compromise in satisfying the diverse requirements of industry and agriculture. Moreover, during this period of priority for the establishment of heavy industry in the countries of Eastern Europe, insufficient resources were devoted to the automotive industry to provide a variety of vehicles.

### *A. Improved Product Assortment*

However, as the automotive industries developed, it became possible to expand product mixes to include more sizes and types of trucks including special forms for parcel delivery, furniture moving, crane and mixer carriers, loose aggregate materials, refrigerated cargo, passenger transportation, and highway express service. Table 3 lists the main characteristics of trucks and passenger cars presently in production in Eastern Europe.

### *B. Popular Motorization*

Moreover, official attitudes toward private ownership of passenger cars changed markedly by 1960. During the 1950s, when economic policy favored rapid industrialization, consumer interests had to wait. The few passenger cars produced each year in Czechoslovakia, East Germany, and Poland were intended primarily for taxi service, government officials, essential services (e.g., doctors), and for export. A few were offered for public sale at very high prices and were acquired by members of the political and cultural elite who paid the full price in advance and then waited several years for delivery.

By 1960, official attitudes on production of cars for private ownership began to soften, partly because the most urgent needs for commercial and official vehicles were being satisfied and partly because something more had to be done for rising consumer expectations and to absorb excess savings. Moreover, there was a perception common to both the Developed West and Eastern Europe that a country could not call itself industrialized if it did not have a substantial program for popular motorization.

Finally, and significantly, it should be noted that each country wanted to produce vehicles for export. Moreover, because they wanted to produce cars that would be acceptable in Western markets they were forced to turn to the West for product design.

As shown in Table 1, production of passenger cars in Eastern Europe has grown substantially in the period since 1960. Moreover shipments of Soviet cars into Eastern Europe have more than compensated for exports from that region. Nevertheless, the waiting lists of hopeful buyers remain long for the more affordable cars, although the more expensive ones are often immediately available but remain unsold because of their high prices.

Car prices in Eastern Europe are administered by the governments (except for Yugoslavia) and are high compared with Western prices. In the U.S., the price of a subcompact (Pinto, Vega, Gremlin) is equivalent to about 4 months earnings for an average industrial worker. The wage equivalent for a comparable small car in Eastern Europe varies from a low of 10 months in East Germany to a high of 47 months in Rumania and Hungary. In addition to relatively low industrial wages in Eastern Europe all the regimes use very high sales (turnover) taxes on cars and other consumer durables as a revenue earning device. These wage-price relationships are reflected in the larger number of registrations per 1000 persons in the population in East Germany compared with Rumania and Hungary, as shown in the following tabulation for 1975. They are also reflected in the fact that waiting lists remain long in East Germany where cars are relatively cheap and demand is high.

REGISTRATIONS OF PASSENGER CARS IN EASTERN EUROPE, U.S.S.R., AND SELECTED WESTERN COUNTRIES,  
BEGINNING 1975

Country	Passenger cars <sup>1</sup> (thousands)	Population <sup>2</sup> (millions)	Cars per 1,000 persons
Bulgaria.....	198	8.7	23
Czechoslovakia.....	1,225	14.7	83

<sup>2</sup> Foreign Demographic Division, Bureau of Economic Analysis, U.S. Department of Commerce.

Demand is particularly high for cars made under Western license—Polski FIAT, Lada (Soviet FIAT), Zastava (Yugoslav FIAT), Dacia 1300 (Romanian Renault-12)—and they bring top prices. In Yugoslavia, Western cars assembled from imported parts are popular, and their market prices are kept relatively high by large tariffs in order that the locally made Zastavas will sell.

During the Western recession, following the Arab oil embargo, Eastern Europe found it difficult to export cars to the West. Supplies of more expensive cars built up in Eastern Europe, and in some cases prices were lowered, while in others bank financing was offered in order to bring more purchasers into the market.

### C. Outlook for Private Ownership

A question has arisen as to whether East European countries will reduce their plans to expand automobile ownership because of rising world fuel prices and the higher costs of importing fuel. In addition to increased deliveries of goods to the U.S.S.R. to pay for Soviet fuel, there are likely to be some hard currency costs for fuel required from the West above amounts that the Soviets have agreed to supply. Romania, which imports no Soviet oil and has recently changed from a net exporter to an importer of oil, may be facing particularly straitened circumstances.

East European regimes have not yet acknowledged a need to reduce plans for popular car sales because of fuel supply problems. It is not likely that a reduction in present levels of sales will take place and some growth will probably occur as ongoing capital investment programs in the auto industry mature into expanded production.

Because it is not important to the national economy that people use their cars in their occupations, rationing of fuel can be accomplished by merely allowing queues to form at the gas stations which are open to the public and by charging higher prices for gasoline.<sup>4</sup>

<sup>4</sup> Generally, private auto owners in Eastern Europe, as in Japan and much of Western Europe, do not use their cars as everyday conveniences. Public transportation will remain the principal means of getting about. Indeed, the percentage share accounted for by automobiles in urban passenger travel in Eastern Europe is probably comparable to the Japanese level (22 percent). Western European shares are higher than for Japan but substantially below the United States (95 percent).

Higher retail prices for gasoline seem not to have effected the eagerness of private persons to become car owners. Eventual ownership remains a goal for most East Europeans, and seems to be more possible every year. However, given the growing constraints on supplies of hard currencies and credit and the need for Western technology and equipment of all kinds, plans for new passenger car production facilities will probably have to be trimmed or delayed. The decision on the amount of trimming and delaying is an integral part of planning for the share of national income that can be allocated to satisfy consumer needs.

Evidence that national planners are concerned with consumer satisfaction is visible in their efforts to offer a variety of passenger car makes and models for popular sale. The assortments in Czechoslovakia and Hungary, for instance, include small numbers of French, Italian, German, and British cars in addition to all makes from the Communist countries.

## VI. ECONOMIC PROBLEMS SOLVED

The inability of the East European countries to satisfy regional needs for motor vehicle production from regional resources has a number of causes. Most importantly, the necessary production equipment, common vendor-supplied parts, and broadly diversified supporting industry is not available in Eastern Europe. The capability of the U.S.S.R. to supply these items is both insufficient to care for East European needs and not at the desired technological level.

Also significant are feelings about the importance of national sovereignty, which have kept the individual countries from supporting the role of the CEMA organization as an instrument to guide and coordinate the development of an integrated regional industry. Cooperation among the countries is of a bilateral nature and consists for the most part of agreements to exchange fixed amounts of parts and vehicles during specific periods.

### *A. Role of the Soviet Union*

The U.S.S.R. shares with its East European neighbors their lack of well developed supporting industries for motor vehicle production. Despite its nearly 50 years of experience in mass producing motor vehicles, the Soviet Union only recently (1971) began a serious program to expand the output of modern automotive production equipment. Presently, this program is confined to a few major types of equipment, mainly automatic transfer machine tool lines. Consequently, the U.S.S.R. is not an adequate source of production equipment. Neither is the U.S.S.R. a source of manufacturing engineering or advanced product design, for both of which the Soviets still rely on Western developments.

However, participation in major Soviet motor vehicle production programs has made it possible for all the participating East European countries to expand their automotive production activities economically. As shown in the following tabulation, each of these countries has established large-scale output for the U.S.S.R. of a small assortment of common motor vehicle components and accessories, most of

which could be adapted to other vehicles in addition to the Soviet VAZ products. The usual volume has been set at 300,000 sets of parts per year.

*Parts Purchased from Eastern Europe for Volga Motor Vehicle Plant (VAZ)*

Country and Parts:

Bulgaria—Batteries, generators, starters, regulators, coils, condensers, oil filters, and air filters.

Czechoslovakia—Carburetors and headlights.

East Germany—Headlights and dual horns.

Hungary—Radios, distributors, panel instruments, door locks, door handles, horns, wiper motors, tire gauges, and bulbs.

Poland—Headlights, backup lights, shock absorbers, circuit breakers, bulbs, direction indicators, and bumpers.

Yugoslavia—Batteries, radiator grilles, piston rings, electrical parts, switches, mirrors, axles, and steering wheels.

Romania—Does not participate.

In payment for these parts, the U.S.S.R. exports VAZ cars to Eastern Europe. The economic benefits for the East European countries are the widening of motor vehicle production activities to economically efficient size and the acquisition of passenger cars for popular motorization. For the U.S.S.R., a major benefit is the opportunity to use elsewhere the investment resources that otherwise would have gone into additional motor vehicle production facilities. The VAZ program has been so successful that a similar cooperative program has been organized for the Kama truck plant.

The East European countries vary considerably in the extent to which they cooperate with the U.S.S.R. Romania, whose industry initially produced Soviet trucks, jeeps, and cars from parts imported from the U.S.S.R., now apparently receives no Soviet help, provides no parts for the VAZ program and declined to build parts for Kama. Moreover, it does not participate in the production of other Communist designed vehicles. Because it produces MAN trucks under license, it buys some MAN engines from Hungary, but this is a Western-based technology exchange.

The Bulgarian industry, on the other hand is solidly linked to the U.S.S.R., not only because it assembles Soviet trucks and cars, principally from imported parts, but because it is expanding the output of major truck components as a vendor to the Soviet industry. It also produces heavy Skoda trucks with Czechoslovak assistance.

Figure 2 shows the pattern of international cooperation of Hungary's motor vehicle industry with both CEMA and Western countries. For example, Hungary has been selling MAN heavy rear axles to Czechoslovakia and receiving Praga hydromechanical transmissions for buses in return. A new contract between the Csepel Motor Vehicle Plant and the West German Zahnradfabrik will give Hungary the technology to produce the modern ZF automatic transmissions.

Except for installing bus bodies on Skoda chassis supplied by Czechoslovakia, and using old GAZ-20 chassis parts to produce vans, Poland's motor vehicle industry is based on modern Western technology. Consequently, Poland is able to supply complete Bendix-Westinghouse air brake systems for the Soviet Kama truck plant.

Czechoslovakia and East Germany have been struggling to maintain technologically independent motor vehicle industries but are finding the process difficult because of their limited resources. Neither is dependent on the U.S.S.R. for technology or parts, but both find a major market there for end products. They exchange passenger car parts with each other extensively but have not found it expedient to mutually standardize the major components of their cars. Czechoslovakia has accepted help in light truck production from Saviem, a subsidiary of Renault. East Germany has avoided foreign help with product design, but it has received manufacturing engineering assistance and production equipment from Western firms among whom Renault is prominent. Both countries are now concerned with modernization of product to maintain Western sales, and both are finding it difficult to mobilize the necessary hard currency to pay for Western technology and equipment.

### *B. Paying for Western Technology*

The difficult problem of payment for Western production equipment in hard currencies is usually solved by the East European producer selling back part of his product to the technology supplier. A typical example of such an arrangement, is the agreement between Poland and Steyr-Daimler-Puch of Austria, whereby Poland's Jelcz plant obtained a license to produce the new series of heavy Steyr trucks and diesel engines, plus technological help in establishing a heavy truck diesel engine plant at Wola.

Up to 1980, Steyr will supply Poland with components, licenses and documentation worth \$100 million and new trucks worth \$70 million. From 1980 to 1990, Steyr is obligated to buy back Jelcz-produced trucks and engines worth \$289 million. Initial credit in the amount of \$239 million was provided to the Bank Handlowy w Warszawie by the Creditanstalt Bankverein and guaranteed by the Austrian state Kontrollbank.

In this typical transaction, Poland received the most modern heavy truck engine technology, help in establishing production of the engines, and help in overcoming a shortage of hard currency. Poland has similar deals with Berliet (France) on buses; Volvo and Kochums (Sweden) on trucks; Leyland (UK), Perkins (UK) and Henschel (West Germany) on diesel engines; Massey-Ferguson (UK) on tractors; Westinghouse (UK) on air brake systems; etc. This buy-back process was present in the establishment of MAN truck technology in Hungary and Romania and in establishing Daimler-Benz and Magirus-Deutz technology in Yugoslavia.

Czechoslovakia's Skoda, Tatra and Praga firms present an alternative source of product design and production engineering within Eastern Europe. However, if Poland, Romania, and Hungary had adopted Czechoslovak technology they would not have generated the hard currency they needed to pay for the production equipment that was only obtainable in the West. Principal agreements between East European and Western firms for cooperation and assistance in motor vehicle production are listed in table 6.

The factors impelling East European countries to turn to the West for passenger car technology also include the need for sales to the

West to pay for production equipment. Thus, Romania pays for tooling, imported parts, and technical assistance for producing the Dacia-1300 (Renault-12) by producing transmissions for Renault vans. The same arrangements figure in the agreements that FIAT has with Poland and Yugoslavia under which these countries produce FIAT passenger cars.

However, there are other advantages to using Western technology. First, the Western products were developed to compete in world markets and are already being sold and serviced throughout the world. Thus, they have a built-in advantage as export products. Secondly, the parent companies are engaged in intensive competition and can be counted on to continually improve their designs. Finally, the parent companies, being large, free enterprise firms, can be counted on as suppliers of any materials and components which the East European countries find difficult to provide domestically.

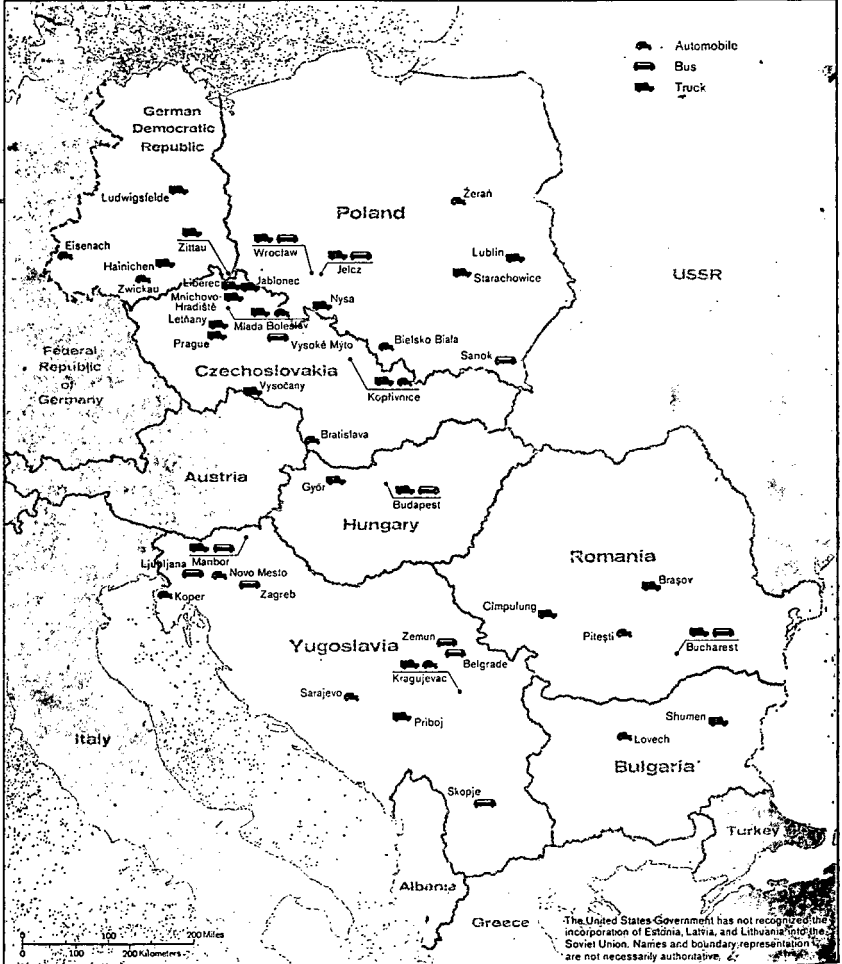

FIAT's assistance to Poland, Yugoslavia, and the U.S.S.R. has ramifications beyond its effect on these countries. In addition to the exchange of FIAT parts bilaterally among these three, FIAT technology is the basis of trade in FIAT parts between Yugoslavia and Egypt, Poland and Ireland, Hungary and Poland, etc. And they all exchange parts with the FIAT home production facility in Turin, Italy.

The difficulties of reaching economical production volumes are being solved by Poland and Yugoslavia through coproduction programs requiring international specialization in the production of FIAT parts. Because Hungary produces FIAT parts for the U.S.S.R., it is able to contract to supply FIAT parts to Poland and take remuneration in Polski-FIATs. (Hungary even exports FIAT parts to Turin.) One might note that in 1974, 36 percent of all cars produced in Eastern Europe were FIAT models. This share has since increased with the growth of passenger car production in Poland and Yugoslavia. If East Germany chooses FIAT technology to replace the outmoded pre-WWII DKW technology now used in its passenger cars, there will be another substantial increase in the share of the "FIAT Club" in total East European passenger car output.

Cooperation with Western firms has allowed the East European motor vehicle industries to expand rapidly, despite major gaps in their domestic supporting industries. Today, these countries participate in the production of a wide assortment of trucks and passenger cars. Their contributions to production from domestic sources are growing and strengthening the import substitution value of their industries.

The rapid introduction into production of the large assortment of types and sizes of trucks, buses, and passenger cars now produced throughout Eastern Europe was possible only with Western technology and equipment. It could not have happened on the basis of East European and Soviet industrial resources and knowhow. A further expansion of cooperational programs with Western firms can be expected. Several major assistance agreements are now in negotiation. Their success will depend only on the ability of East European countries to finance hard currency payments for licenses and equipment.

Introduction.....	420
Population trends since 1950.....	420
Future trends of the population.....	424
Sources, methods, and assumptions.....	430
Appendix tables.....	432

## INTRODUCTION

This paper presents population projections by age and sex for the six Communist countries of Eastern Europe—Bulgaria, Czechoslovakia, East Germany, Hungary, Poland, and Romania. Population trends during the periods 1950 to 1975 and 1976 to 2001 are described briefly in the first two sections of the text. The sources, methods, and assumptions employed in making the projections are discussed in the final section. The text tables present the results of the projections in summary form, some derivative data, and figures relating to the fertility and mortality assumptions. Detailed results for the six countries combined and for each country individually are given in the appendix tables. Table I gives total population on January 1, and July 1, absolute numbers of births, deaths, and natural increase, and the corresponding rates per 1,000 population for each year of the period 1950 to 2000. Table II shows the projected distribution of the population by sex in 5-year age groups for every fifth year of the period 1976 to 2001. The numbers of persons by sex in the preschool, primary school, working, and retirement ages for every fifth year are given in tables III, IV, V, and VI, respectively.

## POPULATION TRENDS SINCE 1950

At the beginning of 1975 the six countries of Eastern Europe had an estimated population of 105,835,000, an increase of 17,769,000 or 20 percent over the total of 88,066,000 in 1950. The population of Eastern Europe grew at a slightly lower rate between 1950 and 1975 than did that of Europe as a whole (table 1). Among the four regions, Western Europe had the highest growth rate for the 25-year period and Northern Europe the lowest. Both of these regions experienced their highest rates during the late fifties and early sixties, whereas Eastern Europe grew most rapidly during the early fifties. The rates for Southern Europe were relatively stable throughout the period.

\*The assistance of Gloria Campbell, Vickey Hart, Kathryn Kuhlman, and Frances Manning of the Foreign Demographic Analysis Division, Bureau of Economic Analysis, U.S. Department of Commerce, in the preparation of this paper is deeply appreciated.

<sup>5</sup> Revised estimates to account for discrepancies between the official estimates and census results. See notes to tables I-C, I-D, and I-F.

Since 1970 there has been a significant decline in the growth rates for Northern and Western Europe and a slight rise in the rates for Southern and Eastern Europe (also see table I-A). The lower rates for the first two regions are due to much lower birth rates as well as less immigration from other areas. The increase for Southern Europe is the result of less outmigration whereas the rise for Eastern Europe is due to higher birth rates. The birth rate for Eastern Europe increased by 10 percent between 1965 and 1975 while the birth rates for Northern, Western, and Southern Europe declined by 28, 34, and 17 percent, respectively. Eastern Europe had the lowest birth rate of any of the four regions of Europe in 1965; by 1975 it had the highest rate. Its rate for 1975 was 48 percent greater than that for Western Europe, which had the lowest rate.

The crude death rate for Eastern Europe reached its low point during the 1960's and then rose gradually during the late 1960's and early 1970's. The rate for Southern Europe declined slightly between 1950 and 1975 while the rates for Northern and Western Europe remained at about the same level during the period. The natural increase rates for Southern and Eastern Europe were higher than those for the other two regions during most of the 25-year period. The 1975 rates for all four regions were considerably lower than the corresponding rates for 1950 and in Northern and Western Europe the 1975 birth rate was only slightly higher than the 1975 death rate.

The population of Eastern Europe represented 22 percent of the total European population in 1975 compared to 17 percent for Northern Europe, 28 percent for Southern Europe, and 32 percent for Western Europe. These percentages are only slightly different from the figures for 1950 (23, 18, 28, and 31 percent, respectively).

Among the six countries of Eastern Europe there was considerable variation in the rates of change. The average annual rates for Poland (1.3 percent) and Romania (1.1 percent) were much higher than the rates for Bulgaria (0.7 percent), Czechoslovakia (0.7 percent), and Hungary (0.5 percent). East Germany had a smaller population in 1975 than in 1950—due primarily to emigration, which was on a very large scale prior to the building of the Berlin Wall in 1961, and to a lesser degree to the fact that the number of deaths exceeded the number of births each year from 1969 through 1975.

The lower growth rates during the 1960's were primarily the result of birth rate declines which began during the 1950's and continued until the mid-1960's, amounting to 30 percent or more in all the East European countries except East Germany. The trends have varied during the past ten years but all of the countries except East Germany had higher rates in 1975 than in 1965.

For the region as a whole, the birth rate dropped from about 24 per 1,000 in 1950 to below 16 in 1966, rose to almost 18 in 1967, declined to 16 in 1972, then increased to almost 18 again in 1975 (table I-A). The increase in 1967 was due to the sharp rise in the birth rate of Romania which resulted from governmental action restricting abortions and the use of contraceptives. The birth rate in Romania was 27 per 1,000 in 1967, almost double the level of 14 in the previous year. After 1967 the rate declined steadily to 18 in 1973 and then rose again to 20 in 1974 and 1975. During the past several years the governments of Bulgaria, Czechoslovakia, and Hungary have also

instituted programs designed to increase fertility, and each of these countries has experienced a recent upturn in the birth rate. On the other hand, after East Germany liberalized its abortion laws in 1972, the birth rate fell to less than 11 per 1,000 in 1973, and remained at that level in 1974 and 1975. Fertility in 1975 was much lower in East Germany than in any of the other five countries, as is shown in the birth rates given in table 1 and the gross reproduction rates<sup>1</sup> given in table 5. The latter rates, which are not affected by differences in age structure, show that fertility is much lower in East Germany than in any of the other five countries.

Mortality also declined after 1950, but not as much as fertility. The death rate for Eastern Europe as a whole decreased from 12 per 1,000 in 1950 to 9 in the mid-1960's, then rose to 11 in 1975. The amount of decline after 1950 was not the same for every country. Poland and Romania experienced the largest declines; for example, in Poland the rate dropped from 12 per 1,000 in 1950 to 7 in 1965. In contrast, for Hungary the 1965 rate was only a little below the 1950 rate and for East Germany the 1965 rate was actually higher than the 1950 rate. The 1975 rates for all of the countries were higher than the corresponding rates for 1965.

The rate of natural increase for the entire region did not vary much during the early fifties, but declined from 13 per 1,000 in 1955 to 6 in 1966. The rate increased to 8 in 1967, decreased to 6 in 1973, then increased again to 7 in 1975. Rates for all six countries fell by more than 25 percent between 1950 and 1965, and those for Bulgaria, Hungary, and Romania dropped by more than 50 percent. Recent trends have varied: in Czechoslovakia, Hungary, and Romania, the natural increase rates were higher in 1975 than in 1965; in Bulgaria and East Germany, the rates were lower; and in Poland, the 1975 rate was about the same as the 1965 rate. In East Germany, the death rate exceeded the birth rate during 1975 by a margin larger than in any other major world country.

Since 1950, all six countries have experienced at least one period of significant net emigration, but East Germany was the only country where migration was the most important factor in population change. Net emigration from that country between 1950 and 1975 amounted to around 2.5 million persons, or more than 13 percent of the 1950 population. Practically all of this emigration occurred before the erection of the Berlin Wall in 1961. Emigration was significant for Bulgaria in 1950 and 1951 when part of the Turkish minority was expelled. There was significant emigration from Czechoslovakia in 1968 and 1969 as a result of the Soviet intervention during August 1968 and from Hungary in 1956 and 1957 as an aftermath of the revolt in late 1956. Poland and Romania had considerable emigration during much of the period, but the peak years were 1957 and 1958 for Poland and 1950 and 1951 for Romania.

The different rates of growth experienced by the six countries resulted in a change in population size ranking between 1950 and 1975. East Germany fell from second place in 1950 to third place in 1975, behind Romania. However, Poland had the largest population in both 1950 and 1975, and in the latter year its population of 33.8 million comprised 32 percent of the regional total.

<sup>1</sup> The gross reproduction rate is defined as the number of females that will be born to 100 women during their reproductive lifetimes if a given set of birth rates by age of mother remains in effect.

Selected age-sex characteristics in 1950, 1975, and 2000 are presented in table 4. Between 1950 and 1975 there was a striking shift toward the older age groups in Eastern Europe. For the region as a whole the proportion of the population under 15 years of age dropped from 26.7 to 23.3 percent and the proportion aged 65 and over jumped from 7.0 to 11.3 percent. Similar changes occurred in each of the six countries. East Germany, which had the lowest proportion under age 15 and the highest proportion aged 65 and over, showed a decline from 22.8 to 21.9 percent at ages 0 to 14 and a rise from 10.6 to 16.3 percent at age 65 and over. Poland and Romania had the highest proportions under age 15 and the lowest proportions in the older ages. For Poland the proportion aged 0 to 14 dropped from 29.4 to 24.1 percent and for Romania it decreased from 28.4 to 25.2 percent. In both countries the proportion aged 65 and over increased from about 5.3 to about 9.4 percent during the 25-year period.

The working age population represented approximately two-thirds of the total Eastern European population in 1950 and 1975. All six countries also had about the same proportion aged 15 to 64 in 1950 and only East Germany showed any significant change between 1950 and 1975. For East Germany the proportion aged 15 to 64 declined from 66.6 to 61.9 percent. Within the working ages there was a shift from the younger ages (15 to 39) to the older ages (40 to 64) in Bulgaria, Hungary, and Romania. The shift was in the opposite direction in East Germany. There the proportion aged 15 to 39 rose from 31.0 to 35.6 percent and the proportion aged 40 to 64 dropped from 35.6 to 26.3 percent. For the region as a whole the proportions were about the same in both 1950 and 1975.

The aging of the population between 1950 and 1975 is clearly evident in the increases in median ages. For the region the median age rose from 28.7 to 31.5 years and all of the countries except East Germany also had higher median ages in 1975. The median age for East Germany declined from 37.3 to 35.1 years, but its 1975 figure was still the highest for any of the six countries.

The number of males per 100 females increased in every country but Bulgaria. The increase for East Germany was especially large, from 79.8 in 1950 to 86.5 in 1975. As a result of heavy military losses during World War II, East Germany had the lowest sex ratio in Eastern Europe. Bulgaria had the highest sex ratios, almost 100 in both 1950 and 1975.

For most of the countries the dependency ratio in 1975 was not very different from that in 1950. Only in East Germany, where the ratio increased from 502 to 617, was there any significant change.

#### FUTURE TRENDS OF THE POPULATION

According to the projections presented here, the population of Eastern Europe is expected to number between 116 million and 130 million by the year 2001 (table 2). The principal determinant of the size of the future population will be the trend in fertility. Four fertility trends are postulated for these projections: high, medium, low, and constant. The amount of population growth expected during the period 1976-2001 is about the same for the medium and constant series. Both show absolute increases of about 17 million and both series indicate an average annual growth rate of 0.6 percent for the

TABLE 2.—PROJECTED TOTAL POPULATION AND AVERAGE ANNUAL PERCENT CHANGE—6 EASTERN EUROPEAN COUNTRIES: 1976 TO 2001

1 The above figures for Jan. 1, 1976, are based on the most recent data available; they are somewhat different from the projected figures for Jan. 1, 1976, given in tables I and II.

25-year period. The high series implies an absolute increase of more than 23 million and a growth rate of 0.8 percent, whereas the low series postulates an increase of only 10 million and a growth rate of only 0.4 percent.

Among the individual countries, Poland is expected to have the largest growth. The medium series projection for that country indicates an average annual growth rate of 0.8 percent between 1976 and 2001, compared to 0.7 percent for Romania, 0.6 percent for Czechoslovakia, 0.5 percent for Bulgaria, and 0.3 percent for Hungary. According to the medium series, East Germany will have almost the same number of people at the end of the century as in 1976. These varying growth rates are expected to produce only one change in the size ranking of the six countries—East Germany will drop from third place to fourth place and Czechoslovakia will move up to third sometime during the late 1990's.

Generally, the growth rates for the individual countries and for the region are expected to be lower between 1986 and 2001 than between 1976 and 1986, due largely to the gradual aging of the population, which tends to raise the crude death rate and lower the crude birth rate. For example, the medium series for Eastern Europe as a whole shows an average annual growth rate of 0.7 percent for the earlier period as compared to 0.5 percent for the later period. Corresponding figures for the other series are 0.9 and 0.8 percent for the high series, 0.5 and 0.3 percent for the low series, and 0.7 and 0.5 percent for the constant series. East Germany is the exception to this general trend—for that country the rates for the medium and high series are higher after 1986 than between 1976 and 1986 and the rates for the low and constant series are about the same during both periods.

Since migration is assumed to be negligible after 1975 for all six countries, the projected growth rate is simply the difference between the birth rate and the death rate. The projected birth, death, and natural increase rates for 1976, 1980, 1990, and 2000 are shown in table 3. The birth rates are generally more variable than the death rates. The crude birth rate depends not only on the assumed level of fertility but also on the age-sex structure of the population, with the most crucial factor being the proportion of women in the prime reproductive ages. For the region as a whole, the percent of women in the age group from 20 to 29 years—the ages of highest fertility—is expected to increase from 15.3 percent in 1975 to around 16.3 percent in 1979, decrease to below 13.5 percent in the early nineties, and then increase to almost 14.0 percent by the end of the century. These changes are reflected in the projected trends in the birth rates. All except the low series show a small rise in the birth rate during the late 1970's, followed by a sustained decline until the early 1990's, and then a small increase during the late 1990's.

The trends for the individual countries vary considerably depending on the assumed level of fertility and on the age-sex structure. The birth rate is likely to increase during the next few years in East Germany and Poland, and the rate for East Germany should continue upward until the mid-1980's. Declining birth rates are expected for both countries during the eighties and continuing on into the nineties. In Bulgaria, Czechoslovakia, Hungary, and Romania, the birth rate is expected to decrease during the next several years. It should reach

its low point about 1985 in Romania and around 1990 in Bulgaria, Czechoslovakia, and Hungary. A rise in the rate is indicated for the last three countries between 1990 and 2000. The rate for Romania is likely to increase between 1985 and the early 1990's and then decline again. The East German rate is likely to remain below the rates for the other countries throughout the projection period.

Not much change is expected in the death rates for Eastern Europe. The rate for the region as a whole is projected to remain between 10

and 11 per 1,000 population for the rest of the century, and, with the exception of the low series for Bulgaria and the high series for East Germany, none of the projections show a change of more than 2 per 1,000 during the period. The rates for Czechoslovakia and East Germany are likely to decline a little between 1976 and 2000. Small increases are indicated for Bulgaria, Poland, and Romania. The rate for Hungary will probably be about the same throughout the 25-year period.

Selected age-sex characteristics projected for 2000 are given in table 4. The age distributions vary according to the projection series because the size of the total population, and especially the size of the under 15 age group, is strongly dependent upon the projected level of fertility. For every country except East Germany, the percent aged 0 to 14 is higher in the high series and lower in the low series in the year 2000 than it is in 1975. In most cases the medium and constant series indicate less change in the proportion under age 15. East Germany is expected to continue to have the lowest proportion in this age group, with all four series showing lower figures in the year 2000 than in 1975.

The working age population will probably represent about two-thirds of the population in the year 2000. The medium series shows proportions of 64 to 67 percent of the total population in ages 15 to 64, and the figures for the other series are all between 62 and 69 percent. Within the working ages the projections indicate a shift between 1975 and 2000 from the younger ages (15 to 39) to the older ages (40 to 64). For the region as a whole the number aged 15 to 39 should drop from 38 percent of the total population to about 35 percent while the number aged 40 to 64 is expected to increase from 28 percent to about 29 to 32 percent. For all six countries, the figures also indicate a decrease in the proportion aged 15 to 39, and Bulgaria and Romania are the only countries for which any series shows a decline in the percentage aged 40 to 64.

Persons of retirement age will probably comprise a larger portion of the population by the end of the century than in 1975 for all of the countries except Czechoslovakia and East Germany. By the year 2000 the proportion of persons aged 65 and over will have risen from around 9 or 10 percent to about 12 to 15 percent in Bulgaria, Poland, and Romania.

The median age is projected to be higher by the year 2000 except for the high series for Bulgaria, Czechoslovakia, and Hungary. For Eastern Europe the median age is expected to increase from 31.5 years in 1975 to somewhere between 32.6 and 36.7 years in 2000. All of the median ages shown for the medium series for the year 2000 are greater than 32 years, and that for East Germany is more than 38 years.

The number of males per 100 females will probably be higher at the end of the century in every country except Bulgaria, and in East Germany the increase will be especially large. By the year 2000 the ratio for East Germany is expected to be almost as high as those for Czechoslovakia, Hungary, and Poland. For the region as a whole all four series show substantial increases in the sex ratio.

Changes in the dependency ratios vary from one series to another because the relative size of the under 15 age group varies with the

TABLE 4.—SELECTED AGE-SEX CHARACTERISTICS OF THE POPULATION—6 EASTERN EUROPEAN COUNTRIES: 1950, 1975, AND 2000

<sup>1</sup> Number of persons under 15 and 65 and over per 1,000 persons of age 15 to 64.

level of fertility. For Eastern Europe as a whole the dependency ratio for the high series is higher in 2000 than in 1975, the ratio for the low series is lower, and the ratios for the medium and constant series are about the same in both years. For East Germany all series show lower ratios at the end of the century and for Bulgaria and Hungary all series indicate higher ratios. For the other three countries the ratios in 2000 for the medium series are not much different from the 1975 ratios.

## SOURCES, METHODS, AND ASSUMPTIONS

The projections presented here are consistent with those published in Bureau of Economic Analysis, "Projections of the Population of the Communist Countries of Eastern Europe, by Age and Sex: 1975 to 2000," *International Population Reports, Series P-91, No. 25*, Washington, D.C., July 1976. They supersede all others for these countries prepared previously by the Foreign Demographic Analysis Division.<sup>2</sup> The projections were based on official data available as of April 1975, but in several instances figures have been updated by using later information. Questions concerning the details of these projections or any other aspect of this report should be directed to the Chief, Foreign Demographic Analysis Division, Bureau of Economic Analysis, U.S. Department of Commerce, Washington, D.C. 20230.

The projections were prepared by the cohort-component method. This method begins with recently reported or estimated distributions of the population, by age and sex, and carries the age-sex structure forward to future years on the basis of various assumptions concerning the components of population change (i.e., births, deaths, and migration). For all of the countries, migration was assumed to be insignificant during the projection period.

Whenever possible, official age-sex distributions were used for the base population, but for some countries it was necessary to use estimated or adjusted distributions. For Bulgaria, the population by single years of age and sex reported for January 1, 1971, was updated to January 1, 1974, and adjusted to accord with the population by 5-year age groups and sex reported for the latter date. The base population for Czechoslovakia was estimated by updating and adjusting the distribution by single years of age from the census of March 1, 1961, to conform to the distribution by 5-year age groups reported for January 1, 1974. For the other countries, official distributions by single years of age were used without modification. The base date for East Germany and Hungary was January 1, 1974; the date for Poland was January 1, 1973; and for Romania it was July 1, 1973. For each country the base population was updated to January 1, 1975, by using reported and estimated data on fertility, mortality, and total population for the intervening years.

Four series of projections incorporating alternate fertility assumptions were prepared for each country. The constant series assumes that fertility will remain at the estimated 1974 level throughout the projection period. The other three series were designed to give a reasonable range of possible future trends in fertility. The assumptions for each series were formulated in terms of gross reproduction rates. The rates assumed for 1975 and 2000 are given in table 5; the rates for the intervening years were obtained by linear interpolation. For each country, recently reported or estimated female age-specific fertility rates were adjusted to yield the number of births for 1974. For each series and each year these adjusted fertility rates were multiplied by

<sup>2</sup> Other recent projections for these countries published by this Division were presented in Godfrey Baldwin, "Projections of the Population of the Communist Countries of Eastern Europe, by Age and Sex: 1972 to 2000," U.S. Bureau of Economic Analysis, *International Population Reports, Series P-91, No. 22*, Washington, D.C., December 1972, and in Paul F. Myers, "Population and Labor Force in Eastern Europe: 1950 to 1998," in U.S. Congress, Joint Economic Committee, "Reorientation and Commercial Relations of the Economics of Eastern Europe," Washington, D.C., U.S. Government Printing Office, 1974.

Constant.....	110	121	74	110	109	129

the ratio of the assumed gross reproduction rate to the 1974 gross reproduction rate to give the projected age-specific fertility rates, which, in turn, were applied to the female population in the reproductive ages to give the projected number of births.

The anticipated fertility levels are related to the estimated gross reproduction rates for 1974. For example, the 1974 rate for East Germany was very low; therefore, between 1974 and 2000 the assumed gross reproduction rates for the high, medium, and low series increase by 62, 35, and 8 percent, respectively. By the year 2000 the assumed gross reproduction rate for the medium series for East Germany is 100, compared with 110 for the other five countries. If mortality is low, a gross reproduction rate of 100 would be only slightly below the level of fertility necessary for the replacement of the population. The high series rates for the other five countries increase during the projection period by amounts that range from 1 percent for Romania to 19 percent for Poland. The low series rates decline by amounts that vary from 17 percent for Poland to 30 percent for Romania. The medium series gross reproduction rate for Czechoslovakia decreases by 9 percent, that for Romania drops by 15 percent, and those for Bulgaria, Hungary, and Poland remain almost constant.

Only one assumption was made about the future course of mortality—that it will decrease at a modest rate throughout the projection period. It was assumed that the decline in mortality would be such that life expectancy at birth would increase by 2.5 years between 1974 and 2000. This was accomplished by using model life tables prepared by Coale and Demeny.<sup>3</sup> These model life tables are divided into four families, each representing a different pattern of age-specific mortality based on the mortality experience of various countries of the world. For present purposes, the families selected were those that most closely matched estimated 1974 survival rates by age for each sex. The rates for 1974 were estimated by adjusting survival rates derived from recently published mortality data, by age and sex, to yield the number of deaths for 1974.

The selection of the family of life tables was made separately for males and females, and it was therefore possible that the tables used for a given country in a given period could come from two different life table families. For each sex, two sets of survival rates were derived from the selected family of tables. The level of mortality

<sup>3</sup> Ansley J. Coale and Paul Demeny, "Regional Model Life Tables and Stable Populations," Princeton N.J., Princeton University Press, 1966.

represented by the first set was such that the implied life expectancy was equal to the estimated 1974 life expectancy as calculated from the adjusted survival rates for 1974. The level of the second set was such that the implied life expectancy was 2.5 years higher than that for 1974. For Czechoslovakia, East Germany, and Poland, the increase in female life expectancy was less than 2.5 years since an increase of that amount for these countries would have pushed the life expectancy for females above the maximum level given in the Coale-Demeny regional model life tables. The differences between the two sets of age-specific survival rates were then added to the estimated survival rates for 1974 to produce the survival rates for 2000. The life expectancies associated with the survival rates for 1974 and 2000 are shown in table 6. Survival rates for the intervening years were calculated by interpolating between the rates for 1974 and those for 2000. These rates were used to calculate the numbers of survivors by age and sex for each year in the projection period.

TABLE 6.—LIFE EXPECTANCIES AT BIRTH, BY SEX—6 EASTERN EUROPEAN COUNTRIES: 1974 AND 2000

Country	1974 (estimated)		2000 (projected)

TABLE 1-B.—ESTIMATED AND PROJECTED TOTAL POPULATION, COMPONENTS OF POPULATION CHANGE, AND VITAL RATES—BULGARIA: 1950-2000

[Absolute numbers in thousands; rates per 1,000 population. Differences between natural increase and year-to-year changes in the population estimates are due, in varying degrees, to migration and discrepancies in the reporting systems. Natural increase may not equal the difference between births and deaths due to rounding. See text for an explanation of the series.]

Year	Population		Natural increase		Births		Deaths

TABLE 1-C.—ESTIMATED AND PROJECTED TOTAL POPULATION, COMPONENTS OF POPULATION CHANGE, AND VITAL RATES—CZECHOSLOVAKIA: 1950-2000

Absolute numbers in thousands; rates per 1,000 population. Differences between natural increase and year-to-year changes in the population estimates are due, in varying degrees, to migration and discrepancies in the reporting systems. Natural increase may not equal the difference between births and deaths due to rounding. See text for an explanation of the series.]

Year	Population <sup>1</sup>		Natural increase		Births		Deaths	
	Jan. 1	July 1	Number	Rate <sup>2</sup>	Number	Rate <sup>2</sup>	Number	Rate <sup>2</sup>
Estimates:

2000	17,483	17,553	140	8.0	322	18.4	182	10.4

<sup>1</sup> The published population totals for the years 1961-70 have been revised downward here to account for the difference of approximately 148,000 between the Dec. 1, 1970, census total of 14,344,987 and the figure for that date implied by the unrevised official estimates. Although this difference could have been due to an undercount in the census or to errors in birth- and death registration, it is more likely due to the underregistration of emigration since the 1961 census. Accordingly, the revised estimates are based on the Mar. 1, 1961, census total and adjustments to the implied annual net emigration figures so as to be consistent with the 1970 census total. These adjustments include the assumption that 60,000 refugees left during the last half of 1968 and 20,000 during the first half of 1969.

<sup>2</sup> Rates for the years 1961-70 are based on the published numbers of births and deaths and the revised midyear population totals. See note 1 above.

TABLE I-D.—ESTIMATED AND PROJECTED TOTAL POPULATION, COMPONENTS OF POPULATION CHANGE, AND VITAL RATES—EAST GERMANY: 1950-2000

[Absolute numbers in thousands; rates per 1,000 population. Differences between natural increase and year-to-year changes in the population estimates are due, in varying degrees, to migration and discrepancies in the reporting systems. Natural increase may not equal the difference between births and deaths due to rounding. See text for an explanation of the series.]

<sup>1</sup> The published population totals for the years 1951-64 have been revised downward here to account for the difference of approximately 212,000 between the Dec. 31, 1964, census total of 17,003,632 and the figure for that date implied by the unrevised official estimates. Although this difference could have been due to an undercount in the census or to errors in birth and death registration, it is more likely due to the underregistration of emigration since the 1950 census. Accordingly, the revised estimates are based on the Aug. 31, 1950, census total and adjustments to the implied annual net emigration figures so as to be consistent with the 1964 census total.

<sup>2</sup> Rates for the years 1951-64 are based on the published numbers of births and deaths and the revised midyear population totals. See note 1 above.

<sup>3</sup> Census of Aug. 31, 1950.

TABLE I-E.—ESTIMATED AND PROJECTED TOTAL POPULATION, COMPONENTS OF POPULATION CHANGE, AND VITAL RATES—HUNGARY: 1950-2000

[Absolute numbers in thousands; rates per 1,000 population. Differences between natural increase and year-to-year changes in the population estimates are due, in varying degrees, to migration and discrepancies in the reporting systems. Natural increase may not equal the difference between births and deaths due to rounding. See text for an explanation of the series.]

<sup>1</sup> The published population totals for the years 1961-70 have been revised downward here to account for the difference of approximately 270,000 between the Dec. 8, 1970, census total of 32,642,270 and the figure for that date implied by the unrevised official estimates. Although this difference could have been due to an undercount in the census or to errors in birth and death registration, it is more likely due to the underregistration of emigration since the 1960 census. Accordingly, the revised estimates are based on the Dec. 6, 1960, census total and adjustments to the annual net emigration figures so as to be consistent with the 1970 census total.

<sup>2</sup> Rates for the years 1961-70 are based on the published numbers of births and deaths and the revised midyear population totals. See note 1 above.

TABLE I-G.—ESTIMATED AND PROJECTED TOTAL POPULATION, COMPONENTS OF POPULATION CHANGE, AND VITAL RATES—ROMANIA: 1950-2000

[Absolute numbers in thousands; rates per 1,000 population. Differences between natural increase and year-to-year changes in the population estimates are due, in varying degrees, to migration and discrepancies in the reporting systems. Natural increase may not equal the difference between births and deaths due to rounding. See text for an explanation of the series.]

Just at a time when the employment of foreign labor is being subjected to a new critical appraisal in the industrial countries of the West, the member countries of the Council for Mutual Economic Assistance (Rat fuer gegenseitige Wirtschaftshilfe—RGW or CMEA)<sup>1</sup> are beginning to deal more closely with the problem of “cooperation in labor resource problems”. In the Master-Program (Komplexprogramm) [1] of the CMEA member countries which was adapted in 1971, the possibility of the exchange of labor is suggested as a form of economic cooperation. Actually the international exchange of workers and the cooperation of labor forces of various CMEA countries for certain projects has already been in effect for several years. But only in the last 3–4 years has there begun to be more interest in this new situation and the accompanying problems and to investigate the possibility of developing this form of cooperation.

The reason for the current interest in the employment of foreign workers is related to the growing utilization of the labor supply in the CMEA countries. In most of the Eastern Bloc countries the growth of the labor force has slowed in the 1970's. Especially in the GDR (German Democratic Republic), Czechoslovakia and in Hungary, but also in certain branches and areas of the Soviet Union, an acute lack of labor is becoming apparent. Only in Bulgaria, Romania and in Poland is the number of the employed in non-agricultural jobs increasing in the 1970's at the same rate as in the 1960's. [2] Because of the varying degree of the utilization of labor reserves, it is plausible to consider the temporary migration of labor as a means of eliminating the labor shortage.

## DEMOGRAPHIC DEVELOPMENT

In this regard, the differing reasons for the successive enlargement of the labor supply in the individual CMEA countries should be

\*Research director, Vienna Institute for Comparative Economic Studies, Vienna, Austria.

<sup>1</sup> The report covers only the European members of the COMECON, namely Bulgaria, Czechoslovakia, the German Democratic Republic, Poland, Rumania, Hungary and the Soviet Union.

considered. Usually only increased employment due to industrialization and uninterrupted economic growth is cited. Between 1950 and 1970 the number of employed actually rose by one-fifth in the Eastern European countries and even by more than two-fifths in the Soviet Union. [3] But a series of demographic factors also had a negative influence on the labor supply.

In contrast to Western Europe, population growth in Eastern Europe and in the Soviet Union slowed noticeably in the 1960's in comparison with the 1950's.

CHART 1.—POPULATION AND AVERAGE ANNUAL RATES OF GROWTH

Region	Number (millions)			Average annual rate of growth per thousand (percent)		
	1950	1960	1970	1950-60	1960-70	1950-70

<sup>1</sup> Bulgaria, Czechoslovakia, GDR, Poland, Romania, and Hungary.

Source: Recent Demographic Trends in Europe and the Outlook Until the Year 2000, ECE, Geneva, August 1974 (duplicated).

Furthermore, the population in Eastern Europe grew more slowly during the 1960's than in the other regions of Europe. Within Eastern Europe, Czechoslovakia with 49 thousandths (.49%) and Hungary with 34 thousandths (.34%) remained under the average for annual Eastern European rates of population growth. In the GDR, the population shrank not only in the 1950's, but further in the 1960's, and in 1970 it had 1.3 million inhabitants less than in 1950. Only in the Soviet Union did the population grow substantially faster than in the rest of Europe in spite of a noticeable slowing in the 1960's.

The population changes indicated here are composed of the natural increase in population and the results of international migration. As in the rest of Europe, the natural population growth decreased between 1950 and 1970 because the birth rates exhibited a long-term downward trend and the death rates were stabilized in the mid-1960's after a long decrease.[4]

CHART 2.—NATURAL POPULATION GROWTH, LIVE BIRTHS, AND DEATHS, 1950-69

[Average annual rates per 1,000 inhabitants]

	Natural population growth			Birth rate			Death rate		
	1950-59	1960-64	1965-69	1950-59	1960-64	1965-69	1950-59	1960-64	1965-69
Eastern Europe.....	11.8	8.1	7.1	22.5	17.5	16.8	10.7	9.4	9.7
U.S.S.R.....	17.4	15.1	10.0	25.8	22.3	17.6	8.4	7.2	7.6

Source: See chart 1.

Birth rates begin to sink after the post-war baby-boom tapered off in the first half of the 1950's. The downward trend continued in most Eastern European countries and the Soviet Union until the end of the 1960's. Not until the beginning of the 1970's did the frequency of births increase briefly again in several CMEA countries. [5] Positive impulses for the labor supply are, however, not to be expected for 15

years, when the children born at the beginning of the 1970's reach a productive age.

The changes in the age structure of the population also had a negative effect on the labor supply. The proportion of the "active population" between the ages of 15 and 59 decreased and the population of the older population over 60 increased substantially.

CHART 3.—AGE STRUCTURE OF THE POPULATION, 1950, 1960, AND 1970

[Proportion of the total population in percent]

	Under 15 years of age	15 to 59 years of age	60 years and older
<b>Eastern Europe:</b>			
1950 .....	26.7	62.4	10.9
1960 .....	28.0	59.0	13.0
1970 .....	24.6	59.8	15.6
<b>U.S.S.R.:</b>			
1950 .....	30.3	61.5	8.2
1960 .....	30.4	60.0	9.6
1970 .....	28.9	59.4	11.7

Source: See chart 1.

Natural changes in the population, especially changes in the birth rate, influence a country's labor supply only after a relatively long period of time. In comparison, the influence of international migrations is more immediate and direct. International migration has exercised a definitely negative influence on the labor supply in Eastern Europe since the end of the Second World War. The net emigration (emigration minus immigration) from the Eastern European countries between 1945 and 1950 amounted to between 2.5 and 3 million people. [6] Between 1950 and 1970, the Eastern European countries (excluding the Soviet Union) lost another 3.6 million inhabitants according to accounts from emigration at the same time that the Western European industrial nations (Benelux, FRG [Federal Republic of Germany], France, Austria and Switzerland) gained 7.7 million inhabitants due to immigration. [4] The emigration losses of the GDR were especially heavy. In the 1950's, the emigration loss surpassed the natural population growth by almost two-and-one-half times, but also in the 1960's, the number of emigrants surpassed the natural population growth by an additional third although emigration decreased considerably after the erection of the Berlin Wall. According to accounts, a total of 2.4 million inhabitants left the GDR by 1970. Therefore, almost 2/3 of the total net emigration from Eastern Europe affected the GDR. However, emigration from Czechoslovakia, Poland and Hungary, although considerably less than in the case of the GDR, was substantial. The streams of emigrants from southern Europe to the Western European countries were the result of economic conditions and were often merely a temporary migration in search of employment opportunity, but the spurts of emigration from the Eastern Block were primarily politically motivated and were, therefore, usually of a permanent nature. Poland and Czechoslovakia each lost 7% between 1950-1970, Hungary 15% of their natural population growth through emigration. However, in the case of Czechoslovakia, the blood-letting of emigration until 1950 was not taken into account in the following chart.

CHART 4.—EMIGRATION AND POPULATION GROWTH 1950-70

## GROWING UTILIZATION OF MANPOWER RESOURCES

The combination of rising employment and the aforementioned negative demographic factors led during the 1960's in Eastern Europe as well as in the Soviet Union to a considerable rise in the general employment quotas (the employed as a percentage of the population).

CHART 5.—POPULATION, NUMBER OF EMPLOYED, EMPLOYMENT QUOTAS 1950, 1960, AND 1970

<sup>1</sup> Number of employed as a percent of population.

Source: Statistical yearbook of the CMEA countries, number of employed in some cases estimated.

In the 1950's, the increase in employment resulted mainly from structural shifts—movement out of agriculture—which left the employment quotas for the most part unchanged (Chart 5). However, in the 1960's, additional segments of the population, mainly women, were absorbed into the employment process. This process was concentrated primarily in the GDR, Czechoslovakia, Hungary and to a lesser extent in Poland, while in Bulgaria and Romania the increase in employment continued to result from shifts out of agriculture, although the overall employment quota decreased.

CHART 6.—DEVELOPMENT OF THE OVERALL EMPLOYMENT QUOTAS IN THE INDIVIDUAL COMECON COUNTRIES <sup>1</sup>

U.S.S.R.....	47.0	46.9	47.5

<sup>1</sup> Number of employed as a percent of population.

Source: See chart 5.

A direct comparison of the overall employment quotas in different countries is difficult because the labor of family members on farms is not at all uniformly measured in the statistics of individual countries. In addition, in the agricultural sector juveniles and many people of a post-productive age are often employed. Seasonal and part-time employment also occur more often in agriculture than in the other economic sectors. For all these reasons the employment quotas are usually higher in the less developed countries with a large agricultural sector than in the developed industrial countries. One cannot, therefore, draw any direct conclusions about the utilization of the labor supply by looking at the employment quotas. On the other hand, the trend of the overall employment quotas in the individual CMEA countries is informative in this (the following) respect.

In the GDR, Czechoslovakia and in Hungary, the labor force reserves have already been exhausted. A further increase in the employment of women is hardly possible in these countries and is also rejected for reasons of demographic politics (the high level of employment of women cuts down the birth rate to below the net production limit.) [3] Currently, a considerable number of people of retirement age are already working in these countries. It is becoming more and more difficult to find workers for important branches of the economy. In Czechoslovakia, e.g., an estimated 300,000 jobs in industry remain vacant because of a shortage of labor. [7]

In the Soviet Union, the situation is less tense. As a result of the great distances and insufficient mobility of the labor force, an acute shortage of labor is apparent however, in many branches, occupations and regions, while in other branches and areas there still are sufficient reserves of labor. In Bulgaria, too, the shortage of labor is limited to certain branches and occupations, while in Poland and Rumania there is even less utilization of the labor supply. [8]

#### EMPLOYMENT OF FOREIGN WORKERS WITHIN THE CMEA COUNTRIES

In this situation it is understandable that individual CMEA countries have already considered for some time solving their problems with the help of foreign labor.

However, the employment of foreign labor in the CMEA countries is not a completely new phenomenon. In the early post-war era, Czechoslovakia had already signed agreements with Poland concerning the use of Polish labor in border areas within the concept of minor border traffic. In addition, as the result of a governmental agreement between Czechoslovakia and Bulgaria, Bulgarian workers were em-

ployed in the early postwar years on the farms abandoned by Germans who left the Sudetenland, but also to an extent in the northern and western coal mines. In 1957, Czechoslovakia signed a new agreement about the employment of Bulgarian laborers, which was then renewed three more times. [9] But it wasn't until the end of the 1960's that the possibility of cooperation in the area of foreign labor began to be explored in more detail. Official agreements about various forms of employment of foreign labor were signed between individual CMEA countries, e.g., between Hungary and the GDR, as well as between Bulgaria and the USSR. Pacts concerning temporary employment within the scope of minor border traffic were signed between Czechoslovakia and Poland, as well as Hungary, and between Poland and the GDR. Czechoslovakia has also recently drafted an agreement with Yugoslavia about the employment of Yugoslavian workers in Czechoslovakia which must still be ratified by the governments. [10] This pact was signed in addition to already existing contracts with Yugoslavian construction companies which are undertaking various construction projects in Czechoslovakia with their own workers and equipment.

The employment of foreign labor in the CMEA territory is, however, of a very modest extent and cannot be compared to the stream of foreign (guest) workers in Western Europe. There are no official statistics regarding the employment of foreign workers within the CMEA. However, the statistical year book of the Republic of Hungary contains the information that in 1973, 12,000 Hungarian workers were employed in foreign countries. [11] This figure probably does not include those commuting across the border (cf. Chart 7). Otherwise, one is dependent on individual figures in the daily press and a few articles in professional magazines which are difficult to combine in a coherent, quantitative outline. According to estimates by Soviet authors, the employment of foreign workers in the CMEA territory did not exceed the limit of 100,000 people at the end of 1973. [7] In the interim, this figure is probably substantially higher and one could view the round figure of 150,000 as realistic (Chart 7).

The majority of the foreign workers are employed in the GDR. Some of them are construction workers and technicians who are working in the GDR or construction projects with their Polish or Yugoslavian construction firms within the framework of the "Export of Construction and Assembly Output", some are Polish workers, often women, who cross the border to work in GDR factories along the border, some are young skilled workers and graduates of middle and trade schools in Hungary and Bulgaria who intend to increase or acquire their qualifications in the GDR. Finally, a sizable number of Poles, and many Bulgarians and Turks as well, work in the GDR because of individual labor contracts, which are, nevertheless, negotiated by official agencies of the exporting country. In the GDR, an estimated 60,000 or 70,000 Poles, Hungarians, Bulgarians and Yugoslavs are currently employed.

In Czechoslovakia Polish and Yugoslavian construction firms with their own laborers and technicians are erecting industrial projects, power stations, dams, bridges and roads, as well as hotels and department stores. Almost 5,000 Polish and 2,000 to 3,000 Yugoslavian construction workers, technicians and administrators are in Czecho-

slovakian territory, but employed by their own companies. Far greater is the number of unorganized individual Polish workers who come mainly from the Wojwod communities (Wojwodschaften) Wwoclaw, Katowice and Rzeszow and who work in the border territories in North Bohmen, North Mahren and in East Slovakia in Czechoslovakian industrial and agricultural firms.

The majority of these workers come to Czechoslovakia in the category of minor border traffic (commuters). Among those crossing the border are many women. Some of these workers even commit themselves with one- and two-year contracts to work in distant Czechoslovakian factories and in that case they are lodged in plant quarters for the duration of the contract. Polish sources estimate the number of border commuters and individually employed workers at from 26,000 to 27,000 people. [12] Also an estimated 2,000 Hungarian border commuters work in Czechoslovakia. In addition, an unknown number of Soviet specialists work in Czechoslovakia. Soviet technicians and engineers are working, e.g., on the construction of the subway in Prague.

The third host country in the CMEA territory is the USSR itself. Until this year mainly Bulgarians found work in the USSR. Among other things, they are employed in the construction of an iron and steel plant, as well as a cellulose project near Ust-Ilim along the Angara. The Bulgarian labor contribution is supposed to be compensated out of shipments from the newly created capacities. Another form is the cooperation agreed upon by Bulgaria and the U.S.S.R. for the procurement of commercial timber in the ASSR of the Komi. There Bulgaria has installed forestry operations in which Bulgarian workers are employed. Last year 12,000 Bulgarians were employed in this way in the USSR, this year their number is supposed to climb between 15,000 and 20,000. [9] A small number of Polish and Yugoslavian construction workers and technicians are working within their own companies in the Soviet Union, where hotel projects, etc., are being completed.

In 1976 in the territory of the Soviet Union, the construction of the Natural Gas Pipeline—Magistrate Orenburg was to be undertaken, with which other CMEA countries are to assist. From 25,000 to 30,000 foreign workers, laborers, technicians, engineers and management from Bulgaria, Czechoslovakia, the GDR, Poland and Hungary are taking part in this giant enterprise for 4 years on Soviet territory. After completion, it is expected to supply natural gas not only to the CMEA countries but also to Western Europe, including Austria. [13] This year and in coming years a total of 40,000 to 50,000 foreign workers will likely be employed in various projects in the Soviet Union.

#### EMPLOYMENT OF FOREIGN WORKERS OUTSIDE OF THE CMEA COUNTRIES

Several CMEA countries also send smaller groups of workers to Western Europe and the developing countries. In the FRG, 14,000 Poles are supposed to have been employed in 1973 in the building sector, mainly within Polish construction companies. [14] Industrial complexes, sanatoriums, nursing homes, office buildings and residential complexes have been erected with the help of Polish labor.

There is no more recent information whether this employment of foreign labor is still taking place. In any case, it can be presumed that because of the economic slump in the FRG, this process has more likely been curtailed, if not stopped altogether. In 1973, 800 Poles were working in Libya and currently 4,000 are reportedly employed there. [15] Nearly one thousand Polish specialists, doctors, graduate engineers, biologists, technicians, laboratory technicians and other professionals are working by reason of special employment contracts outside CMEA, some in the West, but mainly in the developing countries. [16] The other CMEA countries, too, procure screened professionals and specialists for limited employment contracts abroad through special foreign trade organizations (Polytechna in Czechoslovakia, TESCO in Hungary, both organizations for international technical and scientific cooperation). In contrast to the "brain drain" as it is known in the West, where graduate professionals accept positions in foreign countries if they expect greater chances of advancement or higher incomes, many CMEA countries organize their own negotiation of time-limited employment contracts abroad for graduate professionals or otherwise occupationally schooled labor. The foreign trade organization signs the contracts on the one hand with the employer abroad and on the other hand with the citizen who is willing to migrate. He receives only part of his earnings in the foreign "hard" currency, while the remainder is deposited for him in non-convertible native currency in an account at home. Many of these professionals, e.g., doctors, complain that the foreign trade organizations have negotiated poorer conditions with the foreign employer than comparable professionals from other countries.

Smaller groups of workers from Hungary, Czechoslovakia and Bulgaria are working in the West by special permission. In Austria, Hungarians, Poles and Slovaks are working, e.g., in the hotel and restaurant industry as well as skilled workers, fitters, mechanics and welders, e.g., in shipbuilding, in Korneuburg. Here, too, the aforementioned foreign trade organizations appear as intermediaries. [17] Individuals, especially from Poland, are using the more relaxed travel opportunities since 1970 to come to the West as tourists, where they then work for awhile and, after eventually receiving an extension of their travel permit, may be employed for a longer time. According to very rough estimates, there may be from 15,000 to 20,000 CMEA workers employed in the West (developed industrial countries and developing countries combined). Finally, it is also known that the USSR sends a larger number of experts not only to the individual CMEA countries but also beyond the CMEA territory, particularly to several developing countries, however, apparently there have not been any figures published which are geographically more closely defined or at all quantitative. The following estimate of foreign employment in CMEA territory, which is assembled mainly from public CMEA sources, is, therefore, only meant to be a rough estimate for orientation for which we do not claim completeness or exactness.

In Chart 6 and the accompanying information, it was shown that, in the course of the 1960's, the level of employment increased in Eastern Europe as well as in the U.S.S.R. and that work force reserves in several CMEA countries are already extensively exhausted. The varying degree of the utilization of the labor supply in the individual

CHART 7.—ESTIMATE OF THE FOREIGN WORKERS EMPLOYED IN CMEA TERRITORY IN 1975 AND 1976 (NUMBER OF EMPLOYED)

<sup>1</sup> Number unknown.

<sup>2</sup> The number of Yugoslav guest workers in Western Europe (approximately 1,000,000) is not included here.

<sup>3</sup> Within CMEA a total of 144,000-162,000.

CMEA countries has started the discussion in the first place about the possibility of using the temporary migration of labor and also anchored this possibility in the overall program of the CMEA. Chart 7 shows at this point the modest limits of foreign employment to date, which is in no way adequate to ease the right balance among the labor forces of several CMEA countries. In the GDR, which displays the largest employment of foreign workers, its portion of employment is 0.75% at the most, in Czechoslovakia, at the most 0.75%. In the Soviet Union, the employment of foreigners amounts to less than 0.05%. Even in the countries which allow a temporary migration of their workers to other countries, this has a minimal effect on the labor supply. In Poland, which sends the most labor abroad, the portion of the overall employment picture is only 0.5%.

#### PURPOSE OF EMPLOYING FOREIGN WORKERS

In the CMEA countries, therefore, it is emphasized that an improvement in the balance of the labor forces through the temporary migration of labor can neither be the sole nor the main purpose of the employment of foreign workers.[8] This can only be an additional source of assistance which can be meaningful for certain concrete functions, but which would be unimportant for purposes of macro-economic balance. The fact that countries which have a labor shortage allow, nevertheless, temporary migration of workers to other CMEA countries with a view toward other advantages is cited as an argument that the degree of utilization of the labor supply can not be the only consideration in the decisions regarding the employment of foreigners. On the other hand, the still ample labor reserves of Romania are tactfully mentioned because it remains apart for reasons of principle and isn't even participating in the gigantic Orenburg natural gas pipeline project with its own labor, but prefers to make its contribution in equipment.

However, it must be emphasized that, in certain branches or for certain concrete functions, labor assistance could be decisive for the success of a project. Especially the importation of the services of Polish construction firms in the GDR and Czechoslovakia must be emphasized here. Approximately 24 industrial and other construction projects of Polish contracting firms in Czechoslovakia are either already completed or are in the process of completion and contracts for 14 new industrial buildings have been signed. [8] Polish construction companies are providing construction and assembly services in 1976 in the GDR for more than 52 million rubles (\$74,000,000). One example is the work being done for the glass and ceramic industry in the industrial zone Ilmenau, which is supposed to be finished in 1977. Polish construction companies are, furthermore, at work in the cellulose and paper industry and are erecting paper mills in Blankenstein and mills for raw photography print in Weissenborn among other projects. They are also working on a nuclear power plant in northern GDR, on the expansion of brown coal open casting and are completing projects for the chemical industry. Finally, for the Palace of the Republic in Berlin, Polish firms with their own labor are completing the assembly of air and climate control units. [18]

In the opinion of some Eastern authors, the increase in efficiency of the CMEA territory by rational use of natural and economic conditions for production is a more important reason for the international migration of labor than the possibility of attaining equilibrium in the labor force. While putting this fundamental principle into effect, one should naturally heed the interests of the individual countries. Therefore, a concentration of labor in already highly developed industrial areas cannot be agreed to unconditionally because areas which have not been adequately developed would be adversely effected as a result. [8] Therefore, in discussions involving the investment participation of several CMEA countries, the postulate is sometimes upheld that the capital investments should be made wherever the labor supply exists, rather than having the labor come from a neighboring country. The construction of a common cotton mill by the GDR and Poland on Polish territory in Zawiercie in the Kattowitz Wojwod community which was supposed to go into operation in 1975 can be cited as an example. [19] In this common plant "przyjazn-Friendship" with equal participation of both partners, the contributions of both countries flow into a common international property. The GDR provided the project plans, steel constructions, building parts, electronic equipment and climate-control units, the Polish side completed the construction and the assembly with its own labor. The crew of between 2,000 and 2,300 people is composed for the most part of Polish workers, mainly women. The GDR only made several specialists available and provided its share of the management. [20] On the other hand, the construction of industries in the border area of the GDR and Czechoslovakia are also being considered as an alternative solution whereby the labor supply commutes across the border from neighboring Poland and Hungary because fewer employment opportunities are available at the time in their border districts. [9, 21]

In some cases, however, the natural conditions of a location can be so favorable that its use with the help of foreign labor can be to the advantage of both sides. Then a concentration of capital investment in the most suitable location is appropriate. The effectiveness of this procedure is documented by the construction of a cellulose plant with an annual production of 500,000 tons near Ust-Ilim along the Angara in the USSR. The GDR, Poland, Romania, Hungary and Bulgaria participated in the project. In spite of great distances and unusually severe climate conditions (in winter, as low as  $-60^{\circ}$  Celsius; in summer, as high as  $40^{\circ}$  Celsius), the advantages of this location are the presence of high-grade timber reserves for many decades to come, clean water of stable quality, cheap hydro-energy and the existing railroad connection.

Therefore, it is more advantageous to locate the processing phase there, too, than to export the commercial timber into the partner countries for processing. [20]

With the exception of Bulgaria, the CMEA countries named are contributing to this project by shipments of materials in the years from 1972 to 1977 within the framework of a credit connected to this project. Bulgaria, which apparently was unable to commit itself to the delivery of materials, is contributing to the construction

of the project with its labor. After 1979, the contributing countries will receive over the long run a certain portion of the finished products with which their investment will also be repaid. Whether, however, Bulgaria, whose workers must also be continually paid, will receive additional compensation in the form of shipments of finished products (for the added value created by its labor) is not known.

The cooperation between Bulgaria and the Soviet Union for the procurement of commercial timber in the Komi-ASSR is also based on the natural advantages of the location. The USSR made land areas in the Tajga available to Bulgaria where 3 combined forestry operations are to be erected. The Soviet Union is supplying the project plans, building materials, equipment and means of transportation for these plants, Bulgaria is supplying the labor. The investment share of the Soviet Union is 56%, of Bulgaria 44%. Accordingly, the entire commercial timber cut will be divided at the ratio of 1:1.33 between the partners. The timber procuring plants used by Bulgaria remain the property of the USSR. [9, 20]

The same motivation for the employment of workers abroad of the advantage of location because of natural resources applies to the gigantic project of the aforementioned natural gas pipeline from Orenburg in the Ural to the Western border of the USSR, to which all seven member countries of the CMEA are contributing. As many as 30,000 foreign workers from Bulgaria, the GDR, Hungary, Czechoslovakia and Poland will work in five sections, approximately equal in length, of the overall distance of 2,790 km for a period of four years under the most severe climate conditions in the Soviet Union. The Soviet Union is the main investor in the natural gas pipeline, providing the project documentation for the entire project, a gas processing and cleaning plant at the site of the natural gas well, as well as a portion of the pipes with a diameter of 1,420 mm. Romania will contribute its share also through the construction of processing and cleaning plants in Orenburg and through shipments of equipment, but it will not contribute to the construction there with its own labor. All other CMEA partners are assuming the full responsibility for the completed construction of their sections according to the turnkey method, i.e. they are expected to deliver their sections in operational condition. Therefore, the individual participating countries must also bring their complete furnishings, workshops, administrative facilities, machines and equipment, means of transportation, cranes and jack equipment, or erect them at the site. Also all necessary services for their own workers, living, cultural and social facilities, and restaurants, canteens, shops, laundry and cleaning facilities, cinemas and infirmaries with doctors and medical personnel must be brought along with the construction and assembly facilities, or be erected there. Even the care of the crew and their supply of necessary consumer goods is provided by special organizations of the participating countries, which must transport some of the goods from within the USSR, but also some must be transported to the USSR from the native countries. [13, 22, 23, 24, 25, 26, 27]

As compensation, the contributing countries will receive approximately 2.8 billion cbm of natural gas annually beginning in 1979 for a number of years in accordance with their share.

A further motivation for the employment of foreign workers within the CMEA territory is, according to authors from various member countries, the acquisition or perfection of the qualifications of the workers and the exchange of experienced specialists. Thus young workers or graduates of trade or occupational schools can, for example, work for 1 to 3 years in a neighboring country which has a higher technical or organizational standard in a particular branch or at a particular professional level. On the basis of a pact between Hungary and the GDR from 1967, several thousand young Hungarian workers and trade school graduates are receiving further education, increasing or acquiring their qualifications and gathering experience about production and labor organization in factories in the GDR, which they can use after they return to the factories of their native country. At the same time they are the labor force for the foreign factories in the GDR, which can be crucial for the fulfillment of operational plans. In 1974, the agreement was expanded so that in the future several hundred young workers from the GDR could also raise their qualifications and gather experience in certain Hungarian factories which have a high technical standard. [8, 9, 28, 29] Poland also has the opportunity to place young workers for a limited time in factories of neighboring countries in order for them to acquire or raise their qualifications. The training of workers in neighboring countries, even before new factories at home become operational, represents a special variety of this cooperation. [19]

The exchange of specialists among the CMEA countries is supported not only for reasons of the exchange of experience, but also to adjust temporary excesses or shortages in this sector. Cooperation in the areas of science and research requires not only the establishment of coordinating centers in the individual member countries and the dispatch of individual scientists and researchers for a limited time to a neighboring country, but also the establishment of international science and research centers which will receive personnel and technical contributions for their projects from the member countries. [20] The CMEA Institute for Economics and Science in Moscow and the Institute for Atomic Physics in Dubno in the U.S.S.R. are examples of such institutions.

#### PERSONAL MOTIVATIONS

Although the trade press in the CMEA countries is examining closely the various forms of employment of foreign workers and the respective interests of the countries participating in the international agreements, it is extremely limited in its reporting and analysis of the amount and forms of worker compensation and the employment and social conditions of the foreign workers.

In general, workers can only be influenced to sign an employment contract abroad if they are personally motivated to do it. This motivation does not necessarily have to be of a material nature although in the majority of cases a financial advantage is probably connected with the start of a job abroad. One can also imagine that, with the limitations on opportunities to travel abroad, particularly younger

people take the opportunity to go to a neighboring country even if they do not expect a direct financial advantage. In many cases, the thought of the higher economic and technical level of the neighboring country, the chance to advance their professional knowledge and to gather additional experiences through exposure to modern technology are reason enough for them. Furthermore, the acquisition of a foreign language is made much easier and a better choice of goods, especially durable consumer goods, is expected as an additional bonus. Due to the higher economic level of the neighboring country, there are probably higher wages than at home provided that they are equal to their labor colleagues in the neighboring country. This equality is guaranteed not only for wages, but also for the social benefits, working hours and other employment regulations in general. [28] In 1970, 75 percent of the young Hungarian workers, who were working in the GDR by reason of the aforementioned international agreement, already earned a monthly average gross income of more than 500 marks and 23.7 percent earned even more than 700 marks in a month.<sup>2</sup>

It can be assumed that the earnings of the young Hungarian workers in the GDR have increased along with the increase in average earnings in the GDR. However, a sociological study by the Hungarian Labor Ministry of the motivation of the emigrating youths concluded that two-thirds want mainly to acquire professional knowledge and to learn the German language in the GDR. "A relatively small number of the youths go into factories in the GDR because of the attainable relatively higher real wage or for other reasons." [28] To what extent these results reflect the objective opinion of the youths, or have been influenced by the character of the interviewer (experts from the Ministry which organizes the drafting and selection of those willing to emigrate) cannot be determined.

It can also be assumed that workers who are employed within the scope of minor border traffic or by reason of "unorganized" individual employment contracts do not receive any special benefits or allowances in addition to their normal earnings, but that they, nevertheless, receive a higher real wage because of the higher economic standard of the host country than would be possible at home. A Polish daily newspaper reports, e.g., that Polish girls who work in the North Bohemian linen factory Texlen in Trutnov receive the same income as their Czechoslovakian colleagues, namely, 1,500 crowns monthly, and that they often earn more than 2,000 crowns. [12]<sup>3</sup>

Until 1972, they apparently had to change part of this income into zlotys at a special exchange rate and deposit it in Poland, but since 1973 they are able to dispense with the Czechoslovakian crowns they earn as they see fit.

There are probably also additional income bonuses for organized employment abroad on the basis of special international pacts. A youth magazine in the GDR [30] reports in an article about the employment of Polish specialists in an aluminum plant in Calbe, who have been living and working in Calbe since the end of 1972 by reason

<sup>2</sup> According to the exchange rate for non-commercial payments, corrected for relative price trends, 500 marks equals 2,250 Hungarian forints; 700 marks equals 3,150 forints. The average income in Hungary in 1970 was 2,484 forints.

<sup>3</sup> By the same conversion principle as in the previous footnote, that is 2,550 and 3,400 Polish zlotys respectively. The average net wage in the textile industry in Poland was 2,500 zlotys.

of a government agreement, that they have come "because the offer attracted them: they can earn 600 marks, plus daily expenses". Unfortunately, more detailed information about the nature and amount of these daily expenses is not given.

Construction Workers, who are on the job abroad with their companies, receive foreign allowances in addition to their wages. According to Polish newspaper articles, Polish construction workers in the GDR received an average monthly income of about 1,000 marks<sup>4</sup> (in 1972) and an additional 1,500 to 2,000 zlotys in foreign allowances, which were paid out in Poland. [31] Similar additional allowances are also paid to the technicians and management personnel who work abroad. On special construction and assembly projects, extraordinary earnings are obviously made, which can hardly be compared with normal income. In an interview with the director for the preparation of the pipelines in the Czechoslovakian enterprise Hydrostav in Bratislava about his company's participation in the construction of the oil pipeline from the Yugoslavian Adriatic to Hungary and Slovakia on Yugoslavian and Hungarian territory, it was learned that an interval of several months will arise after completion of the previous job before the construction of the Adriatic pipeline can begin: "We cannot pay the special workers enough for interim jobs and they are not interested anyway, so that we have to take leave of them. And it is very difficult to win back a person once he has left the company." [32]

Exceptional procedures are even more valid for jobs in difficult climate conditions. This applies especially to the Orenburg-Gas Pipeline in the USSR. In this giant project, too, the press in the individual CMEA countries often reports about technical and organizational problems of this perhaps largest common enterprise in the CMEA, but only rarely about matters of wages and economic settlement of mutual efforts. Only an article in *Zycie Gospodarcze* [13] provides some insight into the wages of Polish specialists on this construction project. Construction vehicle operators and welders earn almost 600 rubles monthly (the average monthly wage in the USSR is 135 rubles monthly including social benefits). The salaries of engineers and technicians are correspondingly higher, the wages of less qualified workers correspondingly lower. The employee receives half of the wages in Poland in PKO-check,<sup>5</sup> which qualify him for preferred shopping in special stores, likewise he can transfer another quarter to Poland at a favorable exchange. The last quarter of the earnings is supposed to be used on the spot for board, leisure activity, the purchase of durable consumer goods, which can be taken into Poland duty-free, etc. Room and work clothes are without charge.

The current value of monetary earnings in rubles is over 10,000 zlotys monthly according to reports, which is again equal to 16,67 zlotys per ruble at the corrected exchange rate for non-commercial payments. At the same time each employee or his family members in Poland an average of 100 zlotys daily as a separation bonus and,

<sup>4</sup> That is about 5,000 zlotys. The average wage in the construction section in Poland was 2,992 zlotys monthly.

<sup>5</sup> PKO-checks have their face value in U.S. \$, the ruble is being exchanged at the official exchange rate: 1 ruble=1.43 \$ in PKO-checks. For 300 rubles, one receives 429 PKO-checks.

in addition, various premiums and extra pay in rubles and zlotys are intended for quality and work within deadlines. The total earnings are, therefore, to be placed at from 13,000 to 15,000 zlotys. In contrast, the average wage of a Polish construction worker in 1974 was 3,876 zlotys net monthly. The material attraction of reporting to work in the USSR is, therefore, extremely great and it can be assumed that a similar preference for the Orenburg-laborers is also shown in the other participating COMECON countries.<sup>6</sup>

#### PROBLEMS AND INSTITUTIONAL LIMITS OF EMPLOYING FOREIGN WORKERS

The conversion of ruble earnings into an effective zloty wage in the preceding paragraph points to a problem which prevents a more rapid expansion of the employment of foreign workers within the CMEA territory. It is the non-convertibility of the currencies and the unrealistic exchange rates which make it difficult for the individuals who are willing to go to work abroad. Therefore, for each project or group of foreign workers, special regulations must be set up which are more or less advantageous for the guest workers depending upon the urgency. For these and other reasons, a Yugoslavian journalist sees little hope in his report from Moscow for a larger share of Yugoslavian workers in factories of the CMEA countries although, due to the economic depression in the West, the interest in employment abroad in the East has been awakened and several CMEA countries, such as the GDR and Czechoslovakia, would like to hire Yugoslavian labor. "In spite of low personal incomes in the Eastern European countries (in comparison with Western Europe), the problem of how to transfer his earnings back to his own country leaves him little economic attraction to go abroad." [33]

Not until the Czechoslovak government after long hesitation declared that it was prepared to agree to the transfers in dollar currency<sup>7</sup> to Yugoslavia, could an agreement be reached between Prague and Belgrade about the employment of Yugoslav guest workers in Czechoslovakia. The GDR had also shown interest some time ago in the employment of Yugoslavian workers. However, since the GDR would not allow transfers in hard currency, no such agreement could be made. [10]

The difficult currency and finance matters, differences in the rights of workers, questions of social security and the varying level of earnings can better be solved, according to the opinion of Soviet authors, if all compensations are transacted on an international level. In this case, the foreign worker would be paid directly by the organization in the country from which he comes. The legal conditions of the employment and social security laws of his own country would be valid for him and also the question of the methods by which his earnings are transferred home would remain subject to an internal regulation. [9] This principle has obviously been applied to the

<sup>6</sup> There are even considerably stronger wage attractions in the West for jobs in extremely difficult conditions. According to a report in the American magazine "Time" of 8/2/1975, qualified workers on the construction of the Alaska-Pipeline receive between \$5,000 and \$6,000 monthly.

<sup>7</sup> In the clearing transactions, \$1 U.S. is transferred to Yugoslavia for 10 crowns, so that a qualified construction worker receives 300 clearing dollars or 4,100 dinars for 3,000 crowns.

Orenburg project. In the majority of cases, however, the foreign worker signs an individual employment contract with the foreign factory and in this case, all regulations regarding employment and social security rights in the foreign country are applicable although the question of transferring earnings or a portion thereof remains subject to regulation by the two countries.

Soviet authors also point out the problem of the surplus product which is created by the foreign workers. [8, 9] According to Marxist economic theory, the actual work is the only source of value. Even under socialist conditions, the worker only receives a fraction of the value he creates in the form of his wages. In contrast to capitalism, however, no surplus value arises which becomes the property of the capitalist employer, but the surplus product becomes the property of society in various ways and again becomes available to society in the form of publicly financed investments or in the form of public consumption funds (transfer payments and social, health and educational programs).

With employment abroad, the problem arises, first of all, of how to measure the surplus product in the first place. Does one proceed from the average economic norm of the surplus product (rate of profit) of the host country or from that of the country of origin of the foreign worker or perhaps from the norm for the surplus product in that sector? The authors do not provide an unequivocal answer to the question they raise.

Secondly, there is the problem of how the quantitatively measured size of the surplus product should be divided among the contributing countries. The country of origin of the foreign worker can base its claim to the surplus product on the fact that it absorbed the costs of educating the worker, that it provides the social services for his dependents and that he retains the right to social benefits such as social security in his old age in his homeland. On the other hand, the host country, too, provides the foreign worker with social services and, furthermore, the material prospects of his employment must be created in the first place through investments. No concrete solution to this question is offered either, except for the conclusion that it must be solved according to the principle of mutual advantage. [8, 9] It is also not clear whether this is merely a theoretical question or whether, in the negotiations between countries about the employment of foreign workers among individual CMEA countries these questions are to be asked concretely and in the form of accepted mutual settlements are to be compensated.

The whole catalogue of problems that has been listed here indicates that institutional barriers render a substantial increase in the employment of foreign workers improbable. The migration of labor within CMEA territory will probably remain, therefore, merely an additional instrument for the solution of especially precarious labor problems.

#### DIFFERENT PROBLEMS CONCERNING FOREIGN WORKERS IN THE WEST AND EAST

In conclusion, it must be remembered that the employment of foreign workers within CMEA differs in many respects from the problem of guest workers in the West. The scale of the employment of foreign workers in the East is significantly lower, so that one can hardly

speak of an influence of these workers on the economic development of the host country. Whereas in the West, in some developed industrial countries the fraction of guest workers within overall employment is so large that it represents a real growth factor. This may not be as noticeable today, in a time of economic slow-down, but there is no doubt that, until recently, the stream of guest workers played a decisive role in the uninterrupted and relatively rapid economic growth of Western Europe. Also, the motivations for the employment of foreign workers in the CMEA countries has been shown to be far more differentiated than in the West, where it is basically a matter of the attainment of a higher income or the alternative to unemployment or agricultural underemployment in the home country.

In the West, furthermore, the decision to go abroad as a guest worker is a personal matter; in the East, such a decision is subject to governmental regulation because neither entry nor exit is possible without previous consultation between the governments. The oft-criticized discrimination against guest workers in the West seems to occur less often in the East. In principle, the foreign workers are equal to domestic labor in every respect. It also does not seem to be the case that foreigners are employed mainly in unskilled unprestigious and poorly paid occupations and jobs. However, their position does differ from that of the domestic workers because they must live separated from their families for long periods of time and because they are often lodged in billets rather than in their own apartments. Finally, foreign workers in the East are usually employed in compact groups whose inner cohesion and group discipline was organized at home.

Bibliography.....	501

Knowledge of the growth of industrial output in Yugoslavia has always been based on the movement of the official index of industrial production, compiled and published by the Federal Institute of Statistics, and evaluations of the record of growth have necessarily been made on that same basis. In view of the widespread use of the official index, it is surprising that its methodology has never been seriously questioned. Yet as soon as the methodology is investigated, it becomes evident that interpretation of the official index is very difficult and comparisons with the growth rates of other countries, where more conventional methods are used, are almost meaningless.

To facilitate such comparisons, a new sample index of Yugoslav industrial production, calculated by methods commonly in use in the West, has been compiled and is reported in this paper. Several variants of the index are presented, but all of them indicate that the growth of industrial production is overstated by the official index, in the sense that the annual growth rate implied by the official index is higher than the rate which is implied by indexes calculated with more conventional methods. The size of the overstatement varies depending on the variant of the sample index and the period of time over which growth is measured. For the entire period, the official index overstates annual growth rates by one to one and one half percentage points; instead of an annual growth rate of about 10%, the sample indexes indicate rates of somewhat less than 9%. Over the 24 year period, this means that industrial production expanded by a factor of about seven, rather than by the factor of nine implied by the official index.

Comparisons based on the sample index with industrial growth rates in other countries brings Yugoslavia's record in line with experience elsewhere. Taking rough account of the level of industrial development at the beginning of the period, growth of industrial capacity over the

\*The research reported here is part of a longer study on Yugoslav industrialization undertaken while the author was a National Fellow at the Hoover Institution, Stanford University. I am grateful to the Hoover Institution and to the Thomas Jefferson Center Foundation, Charlottesville, Virginia, for their generous support of this work. Rush V. Greenslade, G. Warren Nutter, and Gertrude Schroeder provided valuable comments on earlier drafts of the paper.

\*\*Presently at the University of Miami.

subsequent twenty years fits a pattern observed in a number of other industrialized and industrializing countries. Observation of this relationship provides evidence of the effect of the methodological differences between the official index and conventional measurements on comparisons of growth rates, and shows why comparisons based on the official index are likely to be misleading. According to comparable measurements, industrial growth in Yugoslavia was not exceptional; given the high rates of investment in industry during the period, this record suggests relatively inefficient use of investment resources. More extensive examination of this question than is possible within the space limitations of this paper seems worthwhile.

Before moving on to the main body of the paper, a final caveat is in order. The sample indexes are intended to represent only the growth in productive potential in the Yugoslav industrial sector, and movements of these indexes can in no way be taken to reflect corresponding movements in the well-being of Yugoslav citizens. All of the well-known conceptual shortcomings of aggregate income measures as welfare indexes are seriously compounded in Yugoslavia by endemic price controls, turnover taxes, and other interventions in the market. Furthermore, the sample indexes pertain, of course, to only one sector, and their weighting systems are intended to correspond to relative production costs, not to relative purchase costs. To the extent that the weights accurately reflect production costs, the movements of the sample indexes provide a measure of the increase in the capacity of the industrial sector to manufacture products. The sample index movements reveal nothing about the uses to which those products may be put nor do they show anything about the value of the output to the Yugoslav consumer.

In what follows, the first two sections discuss briefly the official production index and the output data used in its construction. The next section describes the methods used in calculating the sample indexes. Following that are sections treating the results of the calculations, some tests of the properties of the new index, and some aspects of the growth patterns.

## I. THE YUGOSLAV PRODUCTION INDEX

### 1. *General description*

The Yugoslav Federal Institute of Statistics claims that its production index is equivalent to a value added index with annually changing weights. The index for a given year is calculated in two stages. First, an annual relative for each branch of industry is calculated as the weighted sum of the annual relatives of the products included in the branch. Second, the branch annual relatives are aggregated by means of a set of branch weights.<sup>1</sup> The growth of industrial output over longer periods is measured by linking the relevant set of annual relatives. Not only does the annual linking cause incomparabilities with other indexes, the weights used in the official index are open to question.

<sup>1</sup> See Savezni zavod za statistiku (henceforth SZS), *Indeks fizičkom obima industrijske proizvodnje: metodološka i ponderacioni sistem* (Metodološki materijala broj 82), Beograd, 1957.

## 2. Weighting system

From 1952 through 1969, the weights for individual products and for branches of industry were based on the sum of wages and depreciation;<sup>2</sup> since 1970, they have been based on the Yugoslav concept of national income. The relation of the sum of wages and depreciation to value added is more tenuous in Yugoslavia than it is in a capitalist system. First, depreciation rates typically have been below those required to maintain the real value of capital.<sup>3</sup> Second, wages (or personal incomes, as the Yugoslavs prefer to call them) have always been a residual.<sup>4</sup> The size of the residual depends on many factors: turnover tax rates, rates of deductions charged against enterprise earnings, variations in market conditions for different products, and the impact of price controls. The influence of these factors has not been uniform across industrial branches, and the weighting system based on them therefore is distorted in an unknown way.

The methods used for cumulating and assigning weights to product groups and industry branches are a further source of distortion. Weights for product groups are compiled from the financial reports of enterprises which report production of the products in question. The procedure requires arbitrary assignments of costs by enterprises and entails unknown variations in the coverage of the products involved. Branch weights are obtained from the wage and depreciation data for the branches as a whole, and it is not clear whether they are the sum of the weights obtained for the products included in the branch.

The final peculiarity of the Yugoslav weighting system is that the weights are changed every year.<sup>5</sup> While annual changes in weights are required for some indexes,<sup>6</sup> their use causes difficulties in making comparisons with commonly used fixed-weight indexes. Furthermore, certain well-known interpretations of the movement of fixed weight indexes are lost when moving weights are used.<sup>7</sup> The combination of moving weights with the method of computing branch weights seems to be an important source of upward bias in the Yugoslav index.<sup>8</sup>

## II. PRODUCTION STATISTICS

### 1. Collection and aggregation

The output data used in the official index (and in the sample indexes) are collected and published by the Yugoslav Federal Institute

<sup>2</sup> The weights have generally been lagged two years, so that the wage plus depreciation formula held for the years through 1971.

<sup>3</sup> This point has often been emphasized by Yugoslav economists; see, e.g., Branko Suhina, *Amortizacija osnovnih sredstava* (Zagreb, 1970), pp. 39-4. Capital revaluations were carried out in 1953, 1958, 1962, 1966, and 1971; see Nemađ Butaš and Mihailo Puletić, *Priručnik o revalorizaciji sredstava organizacija udruženog rada*, Beograd, 1971, pp. 114 ff. for description. After 1966, depreciation rates were no longer specified by the central authorities; instead, minimum rates were laid down and enterprises were given the authority to set their own rates subject to the minima.

<sup>4</sup> For a summary of the evolution of the computation of personal incomes, see Ivan Paš, "The Development of the System of Distribution of the Social Product and Net Income," *Yugoslav Survey* 11:3 (August 1970), pp. 65-88.

<sup>5</sup> This has been so since the 1957 index was calculated. Before then, 1951 weights were used to compute the index for 1939 and for 1940-53, and 1953 weights were used for 1954-56. See *SZS, Indeks fizičkog . . .* loc. cit.

<sup>6</sup> For example, in the Divisia index. See D. W. Jorgenson and Z. Griliches, "The Explanation of Productivity Change," *Review of Economic Studies* 34:3 (July, 1967), 249-82, and W. E. Diewert, "Exact and Superlative Index Numbers," *Journal of Econometrics* 4 (1976), 115-45.

<sup>7</sup> See G. Warren Nutter, "On Economic Size and Growth," *Journal of Law and Economics* 9 (October 1966), pp. 163-88, for a development of these properties of fixed weight indexes.

<sup>8</sup> The weights used in the index for a particular year are not derived from the wage and depreciation data of that same year, but rather from the data of two years earlier. The reason for this is obscure.

of Statistics. Output is reported by enterprises according to the so-called product nomenclature.<sup>9</sup> The procedure requires that each enterprise report the output of every product it makes which is listed in the nomenclature, regardless of whether the product is classified in the same industry branch as the enterprise itself<sup>10</sup> and regardless of the disposition of the product (further processing, sale, or other use). Because the nomenclature cannot be so detailed that literally every industrial product is listed separately, some aggregation of products takes place at the enterprise levels.<sup>11</sup>

## 2. Technical drawbacks

First, because production is reported at many stages of fabrication, there is double counting of output. Therefore, either the weights used should be good approximations to value added or the index should be based on subsets of products chosen so that double counting is eliminated. The Yugoslav index for industry is comprehensive; officially published subindexes (production equipment, reproduction materials, and consumption goods) do not correspond to different stages of fabrication.

Besides double counting, accuracy of reporting is likely to be variable. It is up to enterprise managers to report production; how carefully they do so will vary from one to another, depending on a number of factors.<sup>12</sup> Mere random variability should not be expected; the Yugoslav planning system and development policy probably introduce a bias in favor of more comprehensive reporting in high priority branches of industry. The extent of variability would also be influenced by factors affecting the costs of monitoring reporting accuracy; for example, better accuracy and coverage should be expected in branches with fewer enterprises, in branches in which a larger proportion of output is produced by enterprises classified in those branches instead of by enterprises outside them, and in branches with greater product uniformity.<sup>13</sup> Inspection of these factors suggests that in 1961 the greatest accuracy should have been observed in the energy and metallurgy branches. Chemicals and electrical products would have fallen in the next group, metal products in the next, and building materials, food products, and textiles in the last.<sup>14</sup> Accuracy in reporting output of new products, presumably would be affected by the same factors.

It is possible that systematic bias is caused by the reporting system, although its quantitative importance cannot be determined on the

<sup>9</sup> Further description and discussion of the following observations will be furnished by the author on request.

<sup>10</sup> Enterprises are assigned to industry branches for accounting purposes on the basis of their principal activities.

<sup>11</sup> The number of entries in the nomenclature for annual enterprise reports, and hence the fineness of detail in which products are classified, grew during the twenty years studied here. In 1957, some 503 items were listed; in 1972, the list contained about 2,300 items. See SZS, *Indeks fizičkom . . .*, p. 5, and SZS, *Nomenklatura proizvoda za godišnji izveštaj industrije* (Metodološki materijali broj 203, Beograd, 1972).

<sup>12</sup> Examples include their attitudes toward reporting output, sanctions for detected inaccuracies, probabilities of detection, and alternate uses of their time. Costs to the authorities of enforcing uniform reporting standards would be high.

<sup>13</sup> For example, the petroleum and petroleum products branch comprised only 3 enterprises in 1968; in that year, there were 243 enterprises in the building materials branch, and the two largest produced on 16% of branch value added. See SZS, *Industrijska preduzeća 1969* (Statistički bilten broj 695), Beograd, 1971.

<sup>14</sup> Branch priorities were established on the basis of investment priorities given in the 1957-61 and 1961-65 Five Year Plans. See "Društveni plan privrednog razvoja Jugoslavije od 1957. do 1961. godine," *Službeni list 53/1957* (prosinca, 1957), pp. 1029-44, and "Društveni plan privrednog razvika Jugoslavije od 1961. do 1965. godine," *Službeni list 53/1960* (prosinca, 1960), pp. 969-97. The number of firms in each branch in 1961 was obtained from SZS, *Statistički godišnjak SFRJ 1963* (Beograd, 1963), p. 177. Rough rankings of branches for degree of product uniformity and proportion of output produced within the branch were made by the author.

basis of available data. Branch shares in total industrial output may be biased according to the completeness of reporting, and those biases should change with changes in the factors affecting coverage. Branch growth rates would be unaffected by the reporting system if there were no systematic changes in those factors and if the product set did not change. Between 1953 and 1971, important increases in the number of enterprises took place in the electric products, chemicals, and printing and publishing branches, and important declines in numbers occurred in the coal and food products branches.<sup>15</sup> It seems likely that the proportion of output reported for a given branch that was produced by enterprises classified in the same branch rose in the process of industrialization, but whether this had any differential effects among branches is conjectural.<sup>16</sup> It also seems likely that the degree of product uniformity declined in branches producing highly fabricated goods, especially metal products, electrical products, and chemicals; relatively fewer new products probably were introduced in the textiles, wood, and food products branches. Taken together, these changes suggest that coverage may have deteriorated in electric products, chemicals, printing and publishing, and, to a lesser extent, metal products; coverage may have improved in coal and food products.

### 3. Other sources of distortion

Besides these technical problems, there may be other distortions in the output data. Yugoslavia's revisionist position and insistence on its interpretation of Marxist doctrine make good economic results particularly important. There is an incentive to overstate production and there are no statistical agencies independent of the state to provide outside checks on the official data. Official data have not shielded clear of reporting poor performance. However, difficulties similar to many of those well-known in Soviet statistics can be noted in the Yugoslav data, suggesting that the statistical service engages in some of the same kinds of practices.<sup>17</sup>

For example, output series are added and dropped, usually without explanation. Sometimes it seems clear that a series is added because the item involved is a new product, but this surely would not apply to such things as gunpowder and bread.<sup>18</sup> The reasons for dropping series are less clear; for example, oxygen production simply disappears from one source after 1962. Second, there is a good deal of ambiguity in the specification of the output series. Ambiguity is particularly important in highly fabricated products, in questions of product quality, and in the use of inadequately specified conventional units for the measurement of the output of some products. Third, coverage of series changes from time to time, and data to link one coverage with another usually are not given. While no set of output statistics is free from some problems of this sort, the existence of motive and opportunity for

<sup>15</sup> Numerically large changes also occurred in electric power (decline), ferrous metallurgy (increase), MBMW (increase), building materials (decrease), textiles (increase), and rubber (increase) branches, but in these cases the changes seemed unlikely materially to affect monitoring costs. Data were obtained from SZS, *Statistički godišnjak FNRJ 1954* (Beograd, 1954), p. 149, and SZS, *Statistički godišnjak SFRJ 1973* (Beograd, 1973), p. 179.

<sup>16</sup> Probably more important for some industry branches was the decline of the handicraft (zanatsvo) sector. Apparently most affected were the food, leather, textiles, and metal and electric products branches.

<sup>17</sup> For discussion of the Soviet case, see Gregory Grossman, "Soviet Statistics of Physical Output of Industrial Commodities: Their Compilation and Quality," Princeton, 1960.

<sup>18</sup> Gunpowder was first reported in 1959, and bread in 1964.

tinkering with the data and certain peculiarities observed in them suggest that some manipulation is done to improve the measured performance of the industrial sector. Nothing can be done about this except to take note of it.

### III. THE NEW INDEXES

The sample indexes are Laspeyres and Paasche quantity indexes. The physical output data upon which these indexes are based were taken from official sources,<sup>19</sup> chosen because they provide continuous coverage of a fairly large number of output series throughout the period from 1952 to 1971. The weights were derived as follows.

Several sets of weights were calculated, all intended to provide estimates of value added in production. One set of weights is based on producer prices for specific individual industrial products.<sup>20</sup> In many, if not most cases, prices were given for individual products; as a result, the weights derived from them had to be imputed to broader product classes in the construction of the index, since the nomenclature groups in which output data are classified generally include more than a single product. The sample indexes based on these weights are called "imputed weight" indexes. The second set of weights is based on unit values of industrial products. Unit values were calculated from Yugoslav data on realized sales values and physical quantities sold.<sup>21</sup> The unit value data provide greater detail than the price data. Furthermore, they are organized more or less along the lines of the nomenclature, so it is possible to determine which products are included in individual product groups. For example, in the calculation of the 1961 unit-value weight for starch products, sales and delivery data for three types of starch products were available in the source; the unit value computed from these data corresponds to a base-year weighted average of the unit values of the three types.<sup>22</sup>

Weights based on these unit values can be assigned to the corresponding output series with more confidence than the price-based weights because of the better information about the products included in the output classes. Sample indexes based on these weights are called "direct weights" indexes. On the whole, the unit-value weights are probably more reliable than the price weights. Unfortunately, unit values can be calculated beginning only in 1959, so there is no alternative to the use of price weights for the construction of a Laspeyres index with a 1952 base.

The weights were developed in three stages. First, the basic information on price or unit value was obtained. Second, turnover tax was eliminated from those values. Third, the resulting figure was adjusted by estimates of the ratio of value added to gross value (net of turnover tax) for the product groups to which the item corresponded.

Turnover tax was eliminated for the following reason. Since Yugoslav enterprises may sell their products on the market, rather than delivering them to a state trading network, there is some question

<sup>19</sup> *Industrija*, published annually by SZS. A full listing of the data and complete citations for these and the weight data are available from the author on request.

<sup>20</sup> Price data were obtained from the CENE series published by SZS.

<sup>21</sup> Unit value data were taken from the *Industrijske proizvodi* series published by SZS.

<sup>22</sup> Full details of these and other computations involved in obtaining weights are available from the author on request.

of the incidence of the turnover tax and therefore of how to treat it when using product price or unit value to estimate product cost and ultimately value added. Incidence depends on the elasticities of demand and supply for the product in question, and different estimates of these elasticities will produce different estimates of the incidence and thereby lead to different conclusions about how to treat the tax in computing weights. It can readily be shown that the smaller the supply elasticity and the greater the demand elasticity, the more heavily the turnover tax is shifted to factors of production (at least in the short run).<sup>23</sup> According to the conventional theory of the self-managed firm, supply elasticities are relatively low.<sup>24</sup> Furthermore, much of the period under study here was characterized by inflationary conditions, and there was considerable government intervention in the market, particularly in setting ceiling prices. Where there was excess demand for its product, a seller in effect would face an infinitely elastic demand curve. For these reasons, and in the interests of simplicity and consistency, the best assumption seemed to be that the turnover tax was borne entirely by factors of production. Therefore, turnover tax was deducted *in toto* from the price or unit value when calculating product cost.<sup>25</sup>

After turnover tax was removed from the price or unit value, the resulting figure was adjusted to provide an estimate of value added. At this point, some aggregation of the output series was unavoidable, because the data on which the adjustments were based were not available on a product-by-product basis. The adjustment data were obtained from a series of statistical bulletins on the performance of enterprises in the social sector which the Federal Institute of Statistics began publishing in 1961.<sup>26</sup> These bulletins contain financial information about industrial enterprises, including the so-called social product (*drustveni proizvod*) of the enterprises, turnover tax paid (*porez na promet*), and costs of purchased materials and services (*materijalni troskovi*). The sum of social product and costs of materials and purchased services corresponds to the gross value of sales of the enterprise; hence, the ratio of social product (net of turnover tax) to the sum of itself and materials costs can be taken as the ratio of value added to product price or unit value (net of turnover tax). The avail-

<sup>23</sup> This can be shown most easily by the use of arc elasticities. If  $p_0$  is the price of the product with no turnover tax and  $p_1$  its equilibrium price after the imposition of the tax, the incidence of the tax can be measured by the ratio of  $p_1$  to  $p_0$ . Let the tax rate be 100t per cent and denote the demand elasticity by  $\eta_d$  and the supply elasticity by  $\eta_s$ .

Then

$$\frac{p_1}{p_0} = (1+t) \left[ \frac{\eta_s - \eta_d}{\eta_s - \eta_d(1+t)} \right].$$

The relevant partial derivatives of this ratio are:

$$\frac{\partial(p_1/p_0)}{\partial \eta_s} = (1+t) \left\{ \frac{-t\eta_d}{[\eta_s - \eta_d(1+t)]^2} \right\} > 0 \text{ for } \eta_s < 0;$$

$$\frac{\partial(p_1/p_0)}{\partial \eta_d} = (1+t) \left\{ \frac{-t\eta_s}{[\eta_s - \eta_d(1+t)]^2} \right\} < 0 \text{ for } \eta_s > 0.$$

Thus, the smaller the supply elasticity, or the greater the demand elasticity (i.e., the more negative it is), the smaller is the ratio of  $p_1$  to  $p_0$ , and the more heavily does the turnover tax bear on the producer.

<sup>24</sup> See Benjamin Ward, "Workers' Management in Yugoslavia," *Journal of Political Economy* 65:5 (October 1957), pp. 373-86, and Jaroslav Vanek, "The General Theory of Labor-Managed Enterprises" (Ithaca, 1970).

<sup>25</sup> During 1961, products whose rates were not otherwise specified were subject to a flat 0.5% tax. This flat rate was ignored in the computations.

<sup>26</sup> The source used for this purpose is *Industrijska preduzeća*, published periodically by SZS.

able data permitted the calculation of this ratio for a number of groups of products in almost all industrial branches.<sup>27</sup> These ratios were then used to adjust the net prices or unit values of those products belonging to the available subgroups.

#### IV. THE RECORD OF INDUSTRIAL GROWTH

##### 1. Overall industrial growth

Industrial production grew at a rapid but diminishing pace from 1952 to 1975. According to the official index, industrial output rose about nine-fold over this period, an expansion which corresponds to an average annual growth rate of 10.0 per cent. According to the sample indexes, the expansion was in the neighborhood of 80 per cent of that claimed by the official index, or a reduction in the annual growth rates of about one to one and one half percentage points per year. The official index and several versions of the sample index are presented in Table 1; average annual growth rates for the period as a whole and for several subperiods are shown in Table 2.

TABLE 1.—INDEX OF INDUSTRIAL PRODUCTION IN YUGOSLAVIA, 1952-75

Year:	Official Yugoslav index (1)	1952 imputed weights <sup>1</sup> (2)	1961 imputed weights <sup>2</sup> (3)	1961 direct weights <sup>3</sup> (4)	Moving weights <sup>4</sup> (5)
1952	100.0	100.0	100.0	100.0	100.0
1953	111.1	102.4	104.5	107.6	102.4
1954	126.3	118.4	118.3	121.6	118.4
1955	147.0	140.0	136.9	140.6	140.0
1956	162.1	154.6	149.4	153.8	154.6
1957	189.2	179.9	172.0	180.8	179.9
1958	209.8	200.0	187.4	200.5	200.0
1959	237.7	217.3	205.5	226.1	217.3
1960	274.3	245.4	232.3	258.6	245.4
1961	294.0	260.2	250.0	275.0	260.2
1962	314.0	281.6	274.4	302.2	284.5
1963	362.7	324.0	311.0	344.4	326.8
1964	421.1	366.9	350.6	398.2	380.2
1965	454.8	389.2	371.5	423.0	404.6
1966	474.4	408.6	392.6	436.6	417.4
1967	473.0	403.6	389.6	428.3	412.0
1968	503.3	420.4	406.3	446.0	433.2
1969	560.2	458.3	440.0	489.0	476.2
1970	611.2	489.0	467.3	518.4	506.7
1971	674.2	522.0	504.3	560.6	549.2
1972	726.8	564.4	533.5	591.4	584.0
1973	770.4	597.7	562.0	617.3	609.6
1974	852.8	653.2	615.0	680.2	672.3
1975	900.6	677.1	636.1	713.9	705.6

<sup>1</sup> Weights derived from 1952 product prices; 1952 product sample.

<sup>2</sup> Weights derived from 1961 product prices; 1952 product sample.

<sup>3</sup> Weights derived from 1961 product unit values; 1952 product sample.

<sup>4</sup> For 1952-61, weights derived from 1952 product prices; 1952 product sample. For 1961-71, weights derived from 1961 product unit values; 1961 product sample. For 1971-75, weights derived from 1971 product unit values; 1971 product sample.

<sup>1</sup> Calculated between terminal years according to the compound interest formula.

Source: Calculated from table 1.

The sample indexes differ in their product coverage, the result of limitations in the availability of price (or unit-value) and output information. Generally speaking, as the point of observation recedes into the past, information diminishes about both components of the indexes. The sample index based on 1952 product prices has the most limited coverage (154 series for different products or sets of products), mainly because of absence of 1952 product price data. By 1961, enough additional information about product prices was available to expand the sample by about one-third (to 208 series, exactly). In contrast, unit values could be obtained for a much larger number of products in 1961 and 1971; coverage of the direct-weights index was restricted not by information about weights, but by lack of data for physical production. The index based on 1961 unit values had a product sample about twice as large for the first decade as did the one based on 1952 product prices (320 series), and that based on 1971 unit values was about  $\frac{1}{2}$  larger (442 series).

Because unit values were not available until 1959, it was possible to calculate only one index with 1952 weights; thus, only one Laspeyres index is available for the first decade of the period. The indexes based on 1961 prices and unit values are Paasche indexes for the first part of the period and Laspeyres for the second. The moving weights index links the 1952 imputed weights index to the 1961 direct weights index at 1961, and then links that index to the 1971 direct weights index at 1971.

Space does not permit full discussion of the reasons for the slower growth of the sample indexes.<sup>28</sup> It does not seem to be the result of the coverage of the sample indexes. Analysis of physical growth rates for products excluded from the samples because weights could not be calculated shows median growth rates fully consistent with the growth rates estimated by the sample indexes. Substitution of official Yugoslav-branch weights, or branch weights based on national income shares, themselves open to criticism on several counts, for the value-added branch weights implied in the sample indexes produces only insignificant changes in the observed growth rates. The higher growth rates of the official index seem to result from the method of calculation, in which branches which include relatively fast-growing products receive progressively heavier weights as time passes, and possibly from the treatment of new products, about which little is known.

<sup>28</sup> A more extensive discussion of these reasons may be obtained from the author.

## 2. The underlying production data

Defects in the production data upon which both the official and sample indexes are based were mentioned above. These defects raise questions about the accuracy of all indexes of Yugoslav industrial production.

The sample indexes are based entirely on production in physical units, most often weight, but also volume, numbers, area, or kilowatts. The official index is based almost entirely on physical units as well, but some series are estimated on the basis of hours of labor or value of output.<sup>29</sup> Units of measurement have the greatest potential for distortion in the sample indexes in metal products, where weight is the most common measure of the production of complex machinery and equipment. The value added weights are expressed in dinars per ton or kilogram; if production costs per ton or kilogram changed systematically because of changes in the kinds of machinery being produced, and if the weights were not changed to reflect these developments, the measurement of output would be biased. Since the sample index is basically a fixed weight index, measurement problems of this kind are potentially important.

Production costs could change for many reasons, apart from changes in factor supplies or technology: machines could become more sophisticated, entailing higher costs per ton; they could be produced with greater precision, with the same result; and so forth. There is little evidence which could form the basis for a judgment on questions of this sort. Another source of changes in production costs, when those costs are expressed in terms of dinars per unit weight, is change in average size of the products involved. *Ceteris paribus*, it is likely that costs per ton fall when the number of units per ton falls and vice versa; adding weight to a machine, given the same production technology, degree of sophistication, and precision, ordinarily would involve only using heavier materials in it, without other changes in costs. There are some data which can be used to get a rough idea of changes in sizes of machinery and equipment; however, these data are fragmentary and generally do not cover the entire period from 1952 to 1971.

For types of machinery for which these data are available, there is little suggestion that the units of measurement introduce net bias for this reason.<sup>30</sup> In transportation equipment, average size for most items rose, which would tend to produce an upward bias in a fixed-weight index where output is measured in tons.<sup>31</sup> Most types of metal- and wood-working machinery also became larger in average size, as did much of textile, leather, building materials, and construction machinery.<sup>32</sup> In agricultural machinery, more individual items for

<sup>29</sup> According to official sources, in 1973 some 95.5% of the output included in the official index was measured in physical terms, 1.8% in hours of labor, and 2.7% in value. In recent years, measurement in hours of labor was most important in shipbuilding and significant in MBMW; measurement in value was most important in chemicals and lumber and wood products. Values are generally expressed in current prices with no effort to correct for inflation; in itself, this practice would impart an upward bias to the official index. See SZS, *Industrija 1973* (Statistički bilten broj 847; Beograd, 1974), pp. 6-7, for a discussion.

<sup>30</sup> The following discussion is based on information drawn from SZS, *Industrijski protzodi 1970* (Statistički bilten broj 717; Beograd, 1972), and from SZS, *Industrija*, various issues.

<sup>31</sup> Average size of trucks, buses, diesel engines for them, diesel and electric locomotives, freight cars, and other railroad coaches and vans rose between 1952 and 1971. Average sizes of tractors, motorcycles and motorcycle engines, and marine engines fell; those of passenger cars and their engines stayed about the same.

<sup>32</sup> For these items, data are available only for 1959-71. During that period, in metalworking machinery, presses and bending and cutting machines became larger; average sizes of grinders, drills, lathes, sharpeners, and the like fell or remained about the same. Woodworking drills, lathes, saws, and sanders all became larger or stayed about the same; combination woodworking machines became smaller. Average sizes of looms, spinning machines, leather working machines, brick and tile making machines, and dumpers rose, and those of rubber-working machines, dredges, concrete mixers, crushing and granulating machines, and bulldozers fell or remained about the same.

which data are available went down in average size than rose, but, as with the other types of machinery, the quantitative significance of this is unknown.<sup>33</sup> The underlying data are neither complete enough nor given in sufficient detail to allow firm conclusions or to justify attempts at quantification, but there seems to be little or no suggestion that a fixed-weight index would be biased upward on this account. Even if the sophistication or quality of the machinery were systematically related to size, the fact that average size apparently changed in both directions would tend to reduce any resulting bias.

Instruments and precision machinery are product groups in the metal products branch in which these questions are potentially important. Unfortunately, much less information is available for these groups. Products from them which are included in the sample indexes usually are measured in numbers of units.<sup>34</sup> In most cases for which data are available, the average unit size of these products fell; a base year weight might understate production costs in these cases.

Electrical products is another branch in which units of measurement could create bias. Again, few data are available to determine whether the units could be suspected to cause net bias. For rotating machinery, measurement is in numbers of units; the available data suggest that underweighting in a fixed-weight index could result.<sup>35</sup> Data for most household electric appliances are less complete than those for other goods, generally pertaining to shorter periods, sometimes terminating before 1971. The available information gives no clear indication of bias in either direction.<sup>36</sup> Altogether, there is little reason to suspect that an overall bias is introduced in the electrical products branch by the units of measurement, at least on the basis of the available information.

Questions of units of measurement arise in a number of additional cases. In lumber and wood products, veneer, plywood, and parquet flooring are entered into the sample index in cubic meters; in each case, information about square meters per cubic meter would be useful in judging whether systematic bias is thereby introduced. The textiles branch presents many similar problems, including the use of conventional, but undefined, units ("effective tons" for yarn and thread), square meters for fabrics without specification of weave, and so forth. The ferrous and nonferrous metallurgy branches contain similar examples (for example, steel profiles and extruded aluminum products are measured in tons). Unfortunately, data which could provide insight into the biases which could be introduced by these units of measurement are not available.<sup>37</sup>

<sup>33</sup> During the 1950-61 period, agricultural machines whose average size fell include barrows, horse-drawn plows, sowing machines, hammer mills, feed choppers, and incubators. The average sizes of fertilizer spreaders, grain combines, and corn huskers rose. Those of tractor-drawn plows, rollers, rakes, elevators, sprinklers, and feed driers stayed about the same.

<sup>34</sup> This includes sewing and accounting machines, typewriters, and clocks. Balances and medical and veterinary equipment are measured in tons, and no data are available for estimating changes in size.

<sup>35</sup> The average power ratings of large (over 70 kw) rotating machines rose between 1952 and 1971; those of medium (1.6-70 kw) and small (less than 1.6 kw) rotating machines fell. No definite conclusion can be drawn on the basis of this information, but one might speculate that increases in size of already large motors and decreases in size of already small ones would both cause increases in unit costs, *ceteris paribus*. The change in power rating of medium size motors could be assumed to have a negligible effect on unit cost.

<sup>36</sup> For these items, measurement is in numbers of units. Between 1965 and 1971, the average power ratings rose for electric irons, electric ranges, hot water heaters, and heater-ventilators; they fell for single-unit hotplates, ventilators, and vacuum cleaners, and stayed about the same for boilers and hotplates with two or more units. Whether the changes observed over this short period of time are representative of longer term trends is unknown. Between 1952 and 1971, the average size of clothes washing machines (in tons per unit) rose, as did that of compressor-type refrigerators (in liters per unit). The average size of clothes dryers (in tons per unit) and absorption refrigerators (in liters per unit) fell. Production of the last two items virtually ceased by 1971.

<sup>37</sup> Details of the differences may be obtained from the author.

In summary, the output are deficient in many respects, one of which is the units of measurement. Fragmentary data for only relatively few products are available for judging whether units of measurement cause bias in the indexes. For those products, largely in metal and electrical products, there seems to be little reason to suspect bias, at least as the result of the units of measurement themselves. Bias arising from changes in the sophistication or precision of products in these branches cannot be judged with confidence on the basis of this data, nor can any conclusion be reached about bias arising from units of measurement in branches where not even fragmentary data exist.

## V. GROWTH BY INDUSTRIAL BRANCHES

### 1. *Yugoslav industrial branches*

The data compiled in Yugoslav statistics and used in computing the official and sample indexes pertain to what the Yugoslav national income accounts term the industry and mining sector. That sector, and the indexes measuring its growth, therefore corresponds to the U.S. industry sector, not to manufacturing. Mining and electric power generation constitute the difference between industry and manufacturing in the U.S. classification. In the Yugoslav industry and mining sector, electric power generation is shown as a separate branch. Mining activities are distributed among the branches of industry which process the ores and other raw materials extracted in mining; coal, iron ore, petroleum, natural gas, nonferrous metal ores, and nonmetallic mineral ores all are reported as part of the output of the industry branches which use them. Besides these, additional differences between the two classifications result from grouping products together in Yugoslav branches which are in different branches in the U.S. system.

### 2. *Branch growth rates*

In the pattern of the rates of growth of individual branches of industry (according to the Yugoslav classification) shown in Table 3, there can be seen two aspects of industrial growth: the effects of the industrialization policy followed, and the importance of older, traditional branches of industry in overall growth. In turn, the effects of several strands of the industrialization policy can be observed: the emphasis placed on growth of energy production, the stress on exploitation of existing natural resources, and the attempt to build up new branches with materials bases in the newly exploited natural resources. For example, petroleum and petroleum products and electric power production are among the leading branches by either index.<sup>38</sup> The petroleum branch includes extraction of crude oil and natural gas, both of which grew very rapidly, reflecting both the policy of rapid development of energy supplies and the objective of exploiting the previously almost untapped reserves of oil and gas. The rapid growth of electric power production also shows the energy policy, as well as Tito's predilection for electrification.<sup>39</sup> In contrast, the coal industry,

<sup>38</sup> Although the sample and official indexes differ in the growth rates recorded for individual branches, there is considerable agreement between them so far as the ranking of the branches is concerned. Spearman rank correlation coefficients of 0.98, 0.95, and 0.94 are obtained for the branch rankings in the three periods shown in Table 3.

<sup>39</sup> See Fitzroy MacLean, *The Heretic* (New York, 1957), p. 61, for Tito's early Leninist views on industrialization.

TABLE 3.—ANNUAL GROWTH RATES,<sup>1</sup> YUGOSLAV INDUSTRIAL BRANCHES

which had been relatively well-developed at the beginning of the period and would fall in the set of "traditional" industries, grew very slowly, the energy policy notwithstanding, reflecting the substitution of other fuels in industry.

The electric products branch is an example of the conjuncture of high priority in the development policy and the building up of a new branch. According to the sample index, its growth rate for the 1952-1975 was the highest of all the branches. Beginning with a very small base (in 1952, it accounted for only about 3 percent of social product originating in the industrial sector), it exhibited very high growth rates in the early years. As the branch matured, however, there was a sharp retardation in the measured rate of growth, as can be seen in the growth rates in the later periods, a pattern to be expected in a branch in which there was rapid introduction of new products. The chemicals branch represents another example of development policy emphasis and small initial base, although in this case there is considerable divergence between growth rates according to the official and sample indexes.<sup>40</sup>

Other branches illustrate some of these same points. At first glance, the relatively slow growth of the metal products branch may be surprising. However, as will be seen below, the growth rate for the branch as a whole obscures very rapid growth in some parts of it, parts which were not highly developed at the outset and which were given relatively high priority in the development policy (particularly transpor-

<sup>40</sup> In part, the differences may be due to differences in coverage. Owing to lack of data for weights, the sample index coverage of organic chemicals and plastics is limited. Consequently, these relatively fast growing products, many of which were introduced in the 1960's, may be underweighted in the sample index. On the other hand, however, the Yugoslav weighting system and the treatment of new products in the index may cause overweighting of the new, fast-growing products, underweighting of the slower-growing inorganic chemicals and more traditional products (paints, pigments, soaps, candles, etc.), and consequent overestimation of the growth rate of the chemicals branch. Although the methodological explanations do not explicitly specify how new products are entered in the index, it may be inferred that they are introduced continuously, as they appear in the product mix.

tation equipment and machinery). Similarly, the very rapid growth of the paper products branch may seem surprising. However, one aspect of the development policy was emphasis on exploitation of timber resources and of industries based on wood, and paper appears to fit that category. The wood products branch itself grew rather slowly, but that seems to be the result of its having been relatively highly developed at the beginning, a traditional line of industrial activity in Yugoslavia.<sup>41</sup> Rubber products is another very fast growing branch, and its record is consistent with the industrialization policy emphasis on transportation equipment.

Among the branches which were relatively important in Yugoslav industry in 1952, ferrous and nonferrous metallurgy were consistently given high priority in the development policy. While neither exhibited unusually high growth rates over the period as a whole, both maintained relatively rapid growth. Furthermore, as the data in the table show, the nonferrous branch was one of the few whose pace of growth actually rose in the last few years of the period. This increase was due largely to very rapid increases in production of aluminum, zinc, and ferro-alloys.<sup>42</sup> The building materials branch also exemplifies the emphasis on developing branches with indigenous raw materials bases. Maintaining a fairly steady growth rate while most branches exhibited retardation, the rank of the building materials branch rose steadily through the period. Much of this growth was due to increases in production of wood-based materials, especially plywood, particle board, and the like.

Finally, note should be taken of the performance of those branches which were reasonably well developed at the beginning of the period but which did not receive high priority in the industrialization policy, particularly food products, textiles, and tobacco. Together, these three branches accounted for about one third of the value of social product generated in the industrial sector in 1952, and the textiles branch was, by this measure, the largest single branch. Although the tobacco branch was another in which the general pattern of retardation was not observed (possibly because of favorable weather in recent years), all three of these branches were near the bottom in measured growth. At that, the growth rate for food products almost certainly overstates the growth rate of production of processed food as a whole because of the displacement over the period of food produced in the handicraft or small scale sector by food produced in the industrial sector. It should also be noted that the overall growth rate for textiles hides some important divergences among components of the branch, to be discussed further in the following section.

### *3. Growth Rates for Revised Product Groups*

The Yugoslav branch classification scheme lumps together in certain branches activities which might better be considered separately. Tables 4, 5, and 6 present growth rates calculated for mining and

<sup>41</sup> The discrepancy in growth rates according to the sample and official indexes seems due to much the same set of causes as in the case of chemicals.

<sup>42</sup> Some average annual growth rates for 1971-75 which indicate the growth in these products are: alumina, 23.1 percent; zinc (crude and powder), 26.1 percent; aluminum ingots, 37.9 percent; refined zinc, 15.8 percent; aluminum alloys, 13.4 percent; ferromanganese, 19.3 percent; ferrochrome, 30.7 percent; and extruded aluminum products, 17.3 percent.

industrial activities classified by a scheme intended to bring out some aspects of industrial growth which are obscured in the official classification.<sup>43</sup>

The main purposes for regrouping the data were to separate mining from the industrial branches and to divide metal products into components. The first of these could be done completely; all mining series were separated from the original branches and recombined into a single index, which shows (see Table 4) that mining grew slowly throughout this period. The relatively slow growth of mining was due mostly to the slow growth of coal and nonferrous metal ores, as shown by the data in Table 5. Iron ore was also slightly below the industrial average. On the other hand, mining of nonmetallic minerals (quartz sand and stone, crude fireclay, crude magnesite, crude feldspar, and crude barites form the basis for this index) and especially crude oil and natural gas grew at very rapid rates. The influence of the extent of development of a branch of activity at the beginning of the period is evident; coal mining, nonferrous metals mining, and iron mining all were relatively well-developed in the prewar Yugoslav economy. The policy of exploiting previously untapped petroleum resources, a policy whose implications extend from the rapid growth rate of the extraction of the crude materials through to the rapid growth of the chemical industry, the development of artificial fibers, and the rest of petroleum-related industrial development, is also clearly seen.

Output data from the metal products branch were used to calculate the growth rates shown in Table 4 for transportation equipment, agricultural equipment, and other machinery, tools, and equipment,<sup>44</sup> and part of intermediate producers' goods. Transportation equipment grew fastest of the subgroups from metal products by a substantial margin. The outputs of trucks, buses, railroad vehicles, and even bicycles all grew very rapidly. On the other hand, for the period as a whole agricultural equipment grew considerably less rapidly than transportation equipment and also less rapidly than other types of machinery. Tractors grew faster than the average for this group (at a little more than twelve per cent per year for the twenty years), but agricultural tools and other machinery and equipment grew slower. From these data, it appears that agricultural machinery and equipment output grew only slightly more rapidly than industrial output as a whole. Given the extremely low level of mechanization in agriculture at the beginning of the period,<sup>45</sup> the relatively low rate of

<sup>43</sup> The footnotes to Table 4 give details of the product series which comprise each of its groups. Note that not all of the output series included in the sample indexes previously reported are included in these new groupings. The growth rates shown in Tables 4, 5, and 6 are based on indexes calculated with 1961 unit value weights.

<sup>44</sup> The list of these categories includes some machinery and equipment from the electric products branch, as the footnote to the table states. Transportation equipment does not include passenger automobiles because of the absence of output data in the early part of the period. Production of passenger automobiles grew very rapidly from an extremely small base in 1955; from 1961 to 1971 the average annual growth rate was more than twenty per cent, and remained at just over fourteen per cent from 1971 to 1975. The omission of this series from the transportation equipment group means that the group's growth rate is somewhat understated. However, the omission would have a relatively small impact on the overall rate for that group, and an even less important impact on the industrial production index as a whole, because of the small weight which the series would have in either total. Even by 1975, after the period of very rapid growth, total passenger car production was still only some 140,000 units, of which nearly one third were produced by assembling parts imported from abroad. See *Savezni zavod za statistiku, Industrija 1975*, p. 34.

<sup>45</sup> At the end of 1951, there were 0.45 tractors per thousand hectares of agricultural land and 84 plows per thousand hectares. See *Savezni zavod za statistiku, Statistički godišnjak FNRJ 1957*, p. 163, and *Statistički godišnjak FNRJ 1954*, p. 116. By contrast, in the United States there were about 13 tractors per thousand hectares of farm land in 1969 and about 7 per thousand in 1940. See U.S. Bureau of the Census, "Statistical Abstract of the United States: 1974," pp. 597, 601, 612. In making the estimates for the U.S., it was assumed that the number of tractors per non-reporting farm was the same as the number per reporting farm; this may bias the 1940 estimate upward relative to the 1969 estimate.

TABLE 4.—AVERAGE ANNUAL GROWTH RATES OF REVISED INDUSTRIAL GROUPS<sup>1</sup>

[In percent]

Group	Period		
	1952-75	1961-75	1971-75

growth of agricultural machinery and equipment indicates a correspondingly low priority for agricultural mechanization. Whether the faster growth in the most recent period means a reversal of this policy is unknown.

Removal of mining from the basic metals branches shows that output of processed ferrous and nonferrous products grew faster than would be indicated by the growth rates of the branches according to Yugoslav definitions. The difference in ferrous metallurgy, however, was small because the growth rate for mining was only a bit lower than for the branch as a whole, and because the weight of mining was relatively small in the branch. The impact on nonferrous metallurgy is considerably greater, and for opposite reasons: nonferrous ore mining grew more slowly than the nonferrous metals branch, and mining was a relatively important part of the branch.<sup>46</sup>

Some additional details are worth noting briefly. The growth rate of the revised chemicals branch is marginally below that of the original branch, apparently as a result of the inclusion of certain chemical products classified elsewhere in the Yugoslav scheme. The removal of clothing from the textiles branch reduces the measured rate of growth of the branch, especially in recent years, indicating that clothing output in industry grew faster than the average for the branch as a whole. Comparison of the growth rate for the original textile branch with those for the revised textiles and allied products group and the clothing and footwear group suggests that clothing was a relatively small part of the original textile branch at the beginning of the period. In turn, part of the reason why the base for clothing in the industrial sector (i.e., in the textiles branch of industry) was small in 1952 was that a substantial fraction of the clothing output was produced not in the industrial sector, but in the handicraft sector. In some lines of production, particularly consumer goods (the case of food products was noted above), handicraft sector production was a substantial part of total output in 1952; during the succeeding twenty years, handicraft production stagnated or declined, so that the growth of industrial sector output of the products involved was, in a sense, only a transfer of production from one sector to another. The rate of growth of the revised clothing and footwear branch is relatively high, partly for the reason just mentioned and partly because of the rapid growth of the rubber footwear. Finally, the inclusion of tobacco products in the food and allied products branch reduces the measured rate of growth in comparison with the original food products branch.

There remains the question of the impact on growth rates of removing the activities which would be considered nonmanufacturing in the U.S. classification. In brief, if mining and electric power production are removed from the index, what is its growth rate? The growth rate for the index entitled All Industrial Products shown in the revised product groups only, so it is not fully comparable with

<sup>46</sup> Because of lack of data for 1961 unit values, copper ore mining, whose output grew at an annual average rate of about 11.5%, could not be included. Its exclusion could, of course, cause understatement of the growth rate of the branch. However, this understatement is offset by the exclusion, for similar reasons, of chrome ore mining, whose output shrank to almost nothing (an average annual decline of 16.5%).

Table 6. was calculated from an index for those products included in the growth rates for industry as a whole that are reported in Table 1. Nevertheless, the effects of the removal of nonmanufacturing activities can be seen here. While mining grew more slowly than industry as a whole, electric power production grew faster; the net effect of their removal is to increase the growth rate for those products which would be considered manufacturing products in the United States, in comparison with the growth rate for all of the products included in the Yugoslav index.

## VI. RETARDATION OF INDUSTRIAL GROWTH

The growth rates for the subperiods shown in Tables 2, 3, and 4 all point to steady and uniform retardation in the rate of growth of industrial production. The pattern can be seen graphically in Figure 1. The first signs of hesitation in the rate of industrial production can be seen around 1961-62, immediately after the inauguration of the Five Year Plan for 1961-65 and the first of the reforms in the economic system. These difficulties apparently were partly responsible for the decision to abandon the Plan and begin work on a Seven Year Plan, intended to span 1964-71, meanwhile resorting to a series of annual plans. Growth revived briefly after 1962, but again slowed in 1965 and 1966, concurrent with the major reforms of those years. An actual decline in production in 1967 was followed by a period of steady growth, but at a lower pace, which lasted through the end of the period studied here.<sup>47</sup>

This pattern is reflected in average annual growth rates for intervals in the period (see Table 7). By either the official or the sample index, the rate of growth in recent years is substantially less than that recorded up to the end of the First Five Year Plan (of the self-management period) in 1961. Growth over the latter period appears to be relatively steady and little pattern can be observed in the annual relatives for the years involved.

<sup>47</sup> The breaks in the pattern of growth which occurred in connection with the reforms were accompanied by substantial changes in the composition of output (see J. H. Moore, "An Index of Structural Change in Output," unpublished ms., Thomas Jefferson Center Foundation, Charlottesville, Virginia, 1977). Because the reforms were accompanied by extensive reforms of prices which had long been controlled, it is possible that the reductions in growth rates resulted from the restructuring of output following on changes in relative prices.

## VII. COMPARISONS WITH OTHER COUNTRIES

The data presented in Table 8 provide a comparison with some noncommunist countries which reported output in time periods which could be compared to the first twenty years in Yugoslavia and whose indexes are methodologically similar to the sample index.<sup>48</sup> According to these figures, only the Republic of Korea and Japan had

<sup>48</sup> Because of differences in weight bases and coverages, as well as remaining methodological differences the growth rates in the table are not fully comparable. All of the countries included in Table 1 report an arithmetic index using some form of value added weights, and coverage is approximately the same as that of Yugoslavia. The footnotes to the table specify the most important differences in coverage and weight bases.

higher growth rates than Yugoslavia; Israel, Mexico, and Venezuela were in the same general range. Of course, the sample of growth rates in the table is highly restricted, and, if comparable data were available for other countries, Yugoslavia's position would probably be further down the list. For example, Egypt, Nicaragua, Panama, Ecuador, the Syrian Arab Republic, and Turkey all reported manufacturing indexes showing higher rates of growth over this period than did Yugoslavia, but the coverages of the indexes or the time periods for which data were reported were so different that including the growth rates in Table 8 would have been misleading.<sup>49</sup>

In interpreting the data in Table 13, it must be remembered that there were wide variations in the 1952 levels of development of the countries shown. As is well known, there is no fully acceptable method for making international comparisons of the level of output. As a very rough indication, we take per capita production of electric power in 1952; this indicator is subject to many obvious qualifications,<sup>50</sup> but it seems acceptable for the purpose of establishing orders of magnitude. Per capita electric power production in Yugoslavia was about 161 thousand kilowatt hours in 1952, a production level on the same order as those of Mexico (198), Venezuela (136), and Panama (110), countries which also had growth rates approximately that of Yugoslavia. Yugoslav per capita electric power production was somewhat smaller than that in Japan (604), which had a higher growth rate, and in Israel (416), which had a slightly smaller growth rate. On the other hand, measured by per capita electric power production, Yugoslavia in 1952 was more developed than the Republic of Korea (31 th. kwh/person), the Philippines (47), and India (22), and recorded a lower rate of output growth than the first and higher growth rate than the second and third.<sup>51</sup> If initial stage of development and subsequent rates of growth of manufacturing output generally are negatively correlated,<sup>52</sup> and if per capita electric power production can be taken to measure stage of development, the Yugoslav record appears to be unexceptional by the standards of the noncommunist countries in the postwar period.

Comparison with other European communist countries and the Soviet Union is more difficult because the indexes reported by all of them employ methodologies significantly different from both the official Yugoslav and sample indexes. With the exception of Hungary,

<sup>49</sup> The growth rates and time periods covered were as follows: Egypt, 13.6% for 1953-69; Nicaragua, 10.3% for 1953-71; Panama, 10.2% for 1953-71; Ecuador, 10.9% for 1953-71; Syria, 10.0% for 1953-71; and Turkey, 11.1% for 1953-66. The coverages of the Nicaraguan and Panamanian indexes were substantially different from those in Table 1. The time periods covered by the other four appeared too different from those in the table to warrant their inclusion.

<sup>50</sup> An ordering of countries by this indicator produces some anomalies; e.g., in 1952 Canada ranks considerably ahead of the United States (4581 th. kwh/person vs. 2943), a result probably due to much higher use of other sources of energy in the U. S. (in fact, per capita consumption of energy in all forms in the two countries was just about the same in 1952). At the same time, the rankings that emerge are plausible; in Western Europe, the rank order was West Germany, Austria, Belgium/Netherlands (combined in the source), France, the Netherlands, Italy, and Denmark. The per capita figures ranged from 621 th. kwh/person to 1171. Electric power production data for all countries were obtained from United Nations, "World Energy Supplies, 1951-1954" (Statistical Papers, Series J, No. 2; New York, 1957), pp. 124-35. Population data for these countries were obtained from U. S. Bureau of the Census, "Statistical Abstract of the United States: 1954" (Seventy-fifth edition; Washington, 1954), pp. 13, 955.

<sup>51</sup> Population data for Yugoslavia were obtained from SZS, *Statistički godišnjak SFRJ 1973* (Beograd, 1973), p. 82.

<sup>52</sup> There is some evidence that this is the case. Taking the logarithm of per capita electric power production as the indicator of initial stage of development, simple regression of the growth rates in Table 1 and those reported in the text on that indicator yielded a coefficient of  $-1.06$  with a standard error of 0.47, significant at the 95% level. If India and Japan, the two outliers, are removed, the coefficient is  $-1.62$  and the standard error is 0.37, again significant at the 95% level. It is interesting that Japan apparently achieved a growth rate greater than its 1952 per capita electric power production would suggest; the opposite was true of India.

all of the official indexes employ gross value weights, a practice which causes well-known distortions in the indexes.<sup>53</sup> The impact of distortions in the indexes of the European bloc countries would require detailed study of the industrial structure in each, a task beyond the scope of this work. Generally, if fast growing products are also those in which there is relatively extensive double-counting of output, or if there is a general tendency to vertical disintegration of industry over a given period of time, a gross weighted index will rise faster than the appropriate net weighted index. While the quantitative magnitudes of the biases are not known with precision, there is a general belief that these indexes are biased upward.

Sources. Yugoslavia: Data underlying table 1. The growth rate is that calculated for the manufacturing sector using direct weights. All others: Statistical Office of the United Nations, *Statistical Yearbook: 1972* (New York, 1973), pp. 154-67, and 1972 Supplement to the *Statistical Yearbook* and the *Monthly Bulletin of Statistics* (New York, 1974), pp. 69-102.

The Hungarian industrial production index weights products by the sum of wages and depreciation, which would approximate the appropriate measure, value, added if wages and depreciation were calculated properly. Because of the absence of a capital market in Hungary, and because the labor market works imperfectly, the weights used probably differ from "true" value added weights. Nevertheless, the Hungarian index should be less susceptible to the upward biases of the gross weighted indexes.

<sup>53</sup> For an excellent discussion of these distortions in connection with the official Soviet index, see Rush V. Greenslade, "Industrial Production in the USSR," in Vladimir G. Tremli and John P. Hardt, eds., "Soviet Economics Statistics" (Durham, N. Car. 1972), esp. pp. 174-9.

The differences in weighting systems are further complicated by differences in the base years adopted by the different countries and by differences in the coverages of the indexes; these disparities are summarized briefly in the footnotes to Table 9. These inconsistencies along with the fundamental differences in weighting systems render quantitative comparisons impossible, but the data in the table provide a qualitative indication of Yugoslav growth in comparison with the bloc countries and the Soviet Union.

TABLE 9.—MANUFACTURING GROWTH RATES AND ELECTRIC POWER PRODUCTION IN SOVIET BLOC COUNTRIES AND YUGOSLAVIA

Country	Average annual growth rate, 1953-71 <sup>1</sup> (percent)	1952 per capita electricity production (kilowatt-hour per person)
Bulgaria.....	12.6	189.4

Official index.....	9.8	593.0
U.S. estimated index.....	8.0	
Yugoslavia.....	9.8	160.7

<sup>1</sup> Calculated between terminal years by the compound interest formula.

<sup>2</sup> Gross output weights, 1954 base for 1960 and earlier; 1962 base for 1961 and later.

<sup>3</sup> Excludes publishing; includes fishing and logging. Gross output weights, 1955 base for years to 1965; 1963 base for 1965 and later.

<sup>4</sup> Includes fishing and repair services. Gross output weights, 1956 base for 1956-60, 1960 base for 1961-70, and 1971 base for 1971.

<sup>5</sup> Excludes publishing. Gross output weights, 1954 base through 1960, 1960 base for 1961-67, and 1967 base for 1968 and later.

<sup>6</sup> Excludes publishing; includes fishing. Gross output weights, 1955 base for 1955-67; 1967 base for 1968 and later.

<sup>7</sup> Weights are sum of wages and depreciation, 1954 base for 1949-57, 1958 base for 1958-61, 1962 base for 1962-67, and 1966 base for 1968-71.

<sup>8</sup> Excludes publishing; includes logging, fishing, maintenance, and repair of passenger cars and household machines and appliances, repair of footwear and knitted goods, film processing, dry cleaning and dyeing, and secondary processing of nonferrous metals. Gross output weights, 1963 base.

<sup>9</sup> The growth rate is calculated from the Central Intelligence Agency index for civilian industrial production, whose coverage approximates that of our indexes for Yugoslavia. The CIA index weights individual products by July 1, 1967 or later prices and aggregates industry branches by 1968 value added weights. See Rush V. Greenslade and Wade E. Robertson, "Industrial Production in the U.S.S.R.," in Joint Economic Committee, Soviet Economic Prospects for the Seventies (Washington, 1973), pp. 271, 280.

<sup>10</sup> Index calculated by deducting mining and electric power production from industry and mining in our direct weights (1961 base) index.

Sources: Growth rates: Same as table 13, except for U.S. estimate of U.S.S.R. See footnote 9 to this table.

When the differences in weights and the stage of development at the beginning of the period (indicated by per capita electricity production) are taken into account, Yugoslav growth measured in the table by the growth of our net weighted index (specifically, the 1961 direct weights index), once again appears to fit into the general pattern, no more and no less. By our crude measure of initial level of development, Bulgaria and Romania started at about the same level as Yugoslavia; their measured growth rates are greater, but are probably biased upward because of their gross weights. Poland and the Soviet Union, both measuring output growth by gross weighted indexes, showed about the same numerical values for growth rate of output as did Yugoslavia. But, again, because of the likely upward bias in their indexes, this apparent equality probably would not hold up if their growth rates were measured on a comparable basis. The U.S. index for the Soviet Union, methodologically more comparable,

seems roughly consistent with this view. According to our measure of initial development level, Czechoslovakia and East Germany were further advanced in 1952 than Yugoslavia, and, when account is taken for the likely bias in their indexes, their growth rates relative to Yugoslavia's again seem to fit the pattern. Hungary's growth rate, based on an index with net weights, is more nearly comparable to Yugoslavia's, and is consistent with its initial stage of development relative to Yugoslavia's.

#### APPENDIX. SOURCES OF DATA FOR SAMPLE INDEXES

Physical output data were compiled from the Savezni zavod za statistiku series *Industrija*, published annually since 1956. The first issue in this series included data for 1939 and postwar years through 1956. After that time, the bulletins give data for each of the most recent three years. In compiling the data, the latest available recorded values for any given year were taken as representing the most up-to-date revisions of the output in each product series. In a few cases, missing data points were estimated by various techniques, usually simple regression of the logarithms of surrounding values on a time variable.

Data concerning industrial prices were taken from the SZS series *CENE* for 1957 (price data for the 1952 weights) and 1962 (for the 1961 weights). Unit values were calculated with data compiled from the SZS series *Industrijski proizvodi* for 1970 (for the 1961 weights) and 1971 (for the 1971 weights). Turnover tax rates were compiled from statutes published in *Službeni list*, the official gazette of the Yugoslav legislature. The data used to adjust costs net of turnover tax were taken from the SZS series *Industrijska preduzeća* for 1969 and 1971. Details about the output data, estimation procedures, and computation of weights are available from the author on request.

## EASTERN EUROPE AND THE BALANCE OF POWER

Eastern Europe, the region where both World Wars and the Cold War originated, occupies a critical position in the European and world balance of power. The course of international politics since the second world war tends to confer added validity to the axiom, whose best known expression was given by Halford Mackinder, projecting imperial control over Eastern Europe as the first and indispensable (although not in itself sufficient) precondition for the attainment of world hegemony: "Who rules Eastern Europe commands the Heartland; who rules the Heartland commands the World-Island; who rules the World-Island commands the World."<sup>1</sup> The establishment and perpetuation of Soviet control over Eastern Europe since the end of World War II has brought about a shift of unequal magnitude in the East-West balance of power to the advantage of the Soviet Union.

The West's most basic foreign and defense policies have since had to be organized with reference to this cardinal strategic fact which holds potentially vital implications for the West's security. The Soviet power monopoly in Eastern Europe has so decisively increased the Soviet preponderance of strength on the continent, and brought the Soviet forces and the Communist system into such ominous proximity to the population and production centers and outer communication lines of Western Europe, as to necessitate the introduction of American power and the establishment of American commitments for the purpose of checking the further westward and southward extension of Soviet power or influence. The presence of Soviet power in key areas of East-

<sup>1</sup> Sir Halford J. Mackinder: "Democratic Ideas and Reality," New York: Holt, Rinehart and Winston, 1942 (2nd ed.), p. 150.

ern Europe, with the resultant pressure upon the security of Western Europe, has made a compensatory U.S. presence in the latter region indispensable.

### *The Locational Factor*

Indeed, from the standpoint of world politics, the prize held by Eastern Europe for the great power which controls it is measured to an important extent in terms of geostrategic location. In this respect the assessment of the strategic value of Eastern Europe to the Soviet Union has evolved along with the over-all assessment of the Soviet power position and intentions in relation to the West. While during World War II and the immediate post-war period the region's strategic function was viewed mainly as defensive, as a Soviet protective buffer against invasions coming from the West, subsequent Soviet policies have increasingly brought to the fore the region's correlative offensive function, as a springboard for further Soviet physical or political advancement or encroachments in Europe. This latter perception has been reinforced by the Soviet pressures and intimidation strategy vis-a-vis Western Europe during much of the Cold War period, and more recently by the offensive buildup of Soviet and Warsaw Pact forces in Eastern Europe over the last few years. While in the present world political and power configuration an outright Soviet and Warsaw Pact attack in Western Europe is unlikely, there remains the distinct probability that this military buildup is intended as a persuasive backdrop for Soviet diplomatic, economic and political policies aimed at fragmenting the power alignments and inducing gradual change in the political structure of Western Europe. A crucial factor enhancing the effectiveness of Soviet strategies and policies toward Western Europe, and necessarily affecting the West European response thereto, is the Soviet geostrategic proximity to Western Europe resulting from the Soviet control of Eastern Europe.

Moreover, the fact of Soviet military proximity to Western Europe has—as illustrated by contemporary historical experience—recurrently had the effect, especially in the context of crises of strategic dimensions, of increasing the effectiveness of Soviet pressures in given crisis theaters and of strengthening the Soviet negotiating posture vis-a-vis the West. This situation also contains a demonstrated potential for undermining Western solidarity and generating intra-coalition pressures in favor of accommodating Soviet demands or interests in other geographic or political areas, particularly those in which the West Europeans do not perceive their own vital interests to be at stake.

From the tactical military aspect—whose importance for military planning increases significantly in the context of superpower strategic parity—Eastern Europe contains a number of positions and areas which have time and again figured prominently in international power politics and diplomacy and in this century's (as well as past) military campaigns: the North German and the Pomeranian and Masurian plains, the Pripet Marshes, the Bohemian Quadrilateral, the Moravian Gate, the Baltic Sea approaches to Scandinavia, Jutland and the communications with the North Sea, the Carpathian chain and passes, the Galati-Focshani Gap, the Lower Danube, the Balkan

mountain range, the land and sea approaches to Constantinople and the Straits, the Vardar-Morava Corridor, the Ljubljana-Trieste Gap and the Istro-Dalmation coast.

The holder of these positions and areas, almost all of which are today under direct or indirect Soviet control, is assured not only of a very strong defensive posture, but also of a greatly enhanced ability to swiftly and efficiently mount offensive operations against other states, or to neutralize them by politico-diplomatic means, elicit from them concessions or compliant behavior, and influence their domestic politics, under the actual or implied threat of mounting such operations. Soviet sensitivity to the politico-military potentialities inherent in control over such areas and positions has in recent years been attested to by the occupation of Czechoslovakia, the disposition of Soviet and Warsaw Pact forces in the Pact's Northern sector—the "Central European front"—the locations of Warsaw Pact joint maneuvers in Eastern Europe, and the ongoing Soviet efforts to establish a naval presence on Yugoslavia's Adriatic coast.

### *The Economic Factor*

The economic potential of Eastern Europe and its contribution to the over-all power position of the Soviet bloc is another key element in the assessment of the East-West power balance. The region's very considerable natural resources, industrial production, manpower reservoir and transportation capacities represent significant additions to those Soviet economic wherewithals that are applied toward generating and expanding Soviet and Warsaw Pact aggregate strength. The command economies of the East European states, with their high rates of reinvestment and industrial growth concentrated in the metallurgical, machine building and mineral extractive and processing sectors, and characterized by an output mix markedly weighted toward industrial as against agricultural and services production and toward heavy industrial as against light and consumer goods industrial production, constitute a sizeable increment to the economic components in the sum of power represented by the Soviet bloc. This continuing process of accretion is made possible by the priority allocation of resources to those sectors of the economy which are most apt to sustain and augment the instruments of power, in their spectrum ranging from the narrowly military through general defense support to industrial and scientific-technological development, and including foreign aid programs, integrated with the bloc's international political strategies.

This pattern of proprietary orientation of economic resources toward power-related utilizations, promoted to the detriment of the East European populations' living standards, is ensured by virtue of the decision-making monopoly with respect to resource allocation arrogated by the Communist Party leaderships. The Communist system of political controls and repression perpetuates this monopoly and precludes an organized and effective assertion of alternative economic programs oriented more toward decentralization of the command economic system, the betterment of the standards of living and a more adequate satisfaction of the consumer expectations and socio-economic aspirations of the region's populations. Economic

reform (as envisaged for example by the Czechoslovak reformers in 1968) in the direction of decentralization, reordering of investment priorities and diversion of resources toward the economic branches related to the production of consumer goods and services, would directly affect the nexus between the economic capacity and the military and international political power instruments of the Warsaw Pact states. Given the intimate connection between economic power and military and international political power, intensified pressures "from below" for economic reform in the East European polities (as well as in the Soviet Union) hold potential implications apt to reverberate in the realm of international power politics and seriously affect the position of the Warsaw Pact therein.

The degree to which the economies of the states of Eastern Europe, their natural resource bases, industrial production and planning are coordinated or integrated with those of the Soviet Union and contribute to the enhancement of its and the Warsaw Pact's over-all power position, as well as the quantum of military expenditures by the East European states, will be assessed in the pertinent chapters of this volume.

### *The Military Factor*

Eastern Europe and its armed forces<sup>2</sup> represent a quantity of eminent significance in the East-West conventional military balance in Europe. The armed forces of the East European member states of the Warsaw Pact—German Democratic Republic (GDR), Poland, Czechoslovakia, Hungary, Romania and Bulgaria—total 1,298,000 men under arms, 12,750 tanks, and 2,400 combat aircraft. The bulk of these capabilities are concentrated in the critical Central European region, where the armed forces of the relevant Warsaw Pact states comprise 906,000 men, 8,000 tanks, and 1,700 combat aircraft.

While these substantial figures are in themselves sufficiently edifying, their significance can better be put in perspective by comparing the aggregate military capabilities (in manpower, tanks and aircraft) of the East European members of the Warsaw Pact, (a) with the corresponding Soviet theater capabilities, thus illustrating Eastern Europe's contribution to over-all Soviet bloc conventional capabilities in Europe, and (b) with the corresponding theater forces of the West European members of NATO, thus measuring against each other their respective theater warfare capabilities.

The first of these comparisons, involving the size of the East European conventional theater forces as against the Soviet Union's own (the latter consisting of the Soviet forces stationed in the states of Eastern Europe and in the Western military regions of the Soviet Union abutting on its Western borders) shows the great augmentative contribution made by Eastern Europe to Soviet theater forces. The armed forces of the East European states, in the aggregate, add their 1,298,000 soldiers to the Soviet Union's 775,000 (an increase of 167%); almost doubling the number of Soviet tanks, by adding 12,750 to the 13,750 Soviet tanks; and markedly increasing the number of

<sup>2</sup> Figures in this section are compiled from International Institute for Strategic Studies (London): "The Military Balance 1976-1977," London 1976, pp. 99-104. The count of tanks and aircraft refers throughout to main battle tanks in operational service and tactical combat aircraft in operational service. No attempt is made here at a speculative assessment of such unquantifiable elements in the calculus of military power as command quality, troop reliability and morale and the like, although the importance of these unquantifiable elements is obvious.

Soviet aircraft, by adding 2,400 to the 2,900 Soviet aircraft (an increase of 83%). It is true, however, that the share of Eastern Europe in over-all Soviet bloc theater forces would diminish in the event of actual conflict in Europe, when large Soviet forces would undoubtedly be brought in from the Soviet interior military regions, and the resupply capacity of the Soviet military industry—on which the East Europeans are largely dependent for their hardware—would probably be preempted by the Soviet Union's own forces.

The second of these comparisons involves, on an East European versus West European basis, the East European conventional forces on the decisive Central European front measured against those of the West European members of the NATO alliance (including Britain and France) stationed in the same area—the area with which the M(B)FR negotiations are concerned. This finds the East European forces inferior in manpower: 588,000 vs. 767,000 (a 31% margin), but greatly superior quantitatively both in tanks: 7,800 vs. 4,225 (an 84% margin), and in aircraft: 1,700 vs. 1,010 (a 69% margin). With respect to artillery, the available figures refer to Warsaw Pact and NATO totals in the Northern and Central European sector and show the Warsaw Pact with 5,600 artillery pieces vs. 2,700 for NATO (a ratio of over 2:1). While this superiority of materiel may be offset in the event of conventional conflict in Europe by the additional Western forces apt to be brought to the Central front, in peacetime the massive East European forces stationed in their sector serve to supplement the Soviet forces present in this critical area and compound the pressures exerted upon the security of Western Europe, a situation with potential implications of political rather than military order. The military value of the East European forces on the Central front in relation to their West European opposites would undoubtedly be magnified, as would be their political value, in the event of U.S. force reductions in Europe.

#### *The Political Factor*

The power system of which Eastern Europe represents so important a part is affected by inherent weaknesses and potential vulnerabilities of a political nature. True, the Communist alliance system is cemented by the commonly shared ideology motivating the ruling Communist groups—an aspect of determinative importance from the standpoint of alliance cohesion at the political leadership level. However, the effectiveness of the Soviet and the Communist regimes' efforts to harness Eastern Europe's populations and gear the region's societies to the goals and purposes of the Communist system and Soviet international objectives is open to serious question. A full generation after their installation in power, the East European Communist regimes are faced with persistent failure in their endeavors to elicit popular allegiance and establish legitimacy for their rule, and symptoms of latent political instability have surfaced anew in most of the region's states in recent years. A compounding fact, recorded by many observers, is that the populations of Eastern Europe remain the most pro-Western in the world outside the West itself, and that the U.S. commands here sympathies and prestige to an extent not in evidence elsewhere.

This situation can not but have adverse consequences on the political cohesion of the Communist alliance and, potentially, on the

reliability of its political rear and on the security of the Soviet forward base areas and lines of communication with the Central European front, and ought to be taken into account in the calculation of the East-West over-all relationship of forces at any time. Moreover, in the contingency of new international tensions arising in or over Western Europe (be it over its Central, Southern or Northern areas), the potentialities inherent in the situation of latent political instability prevailing in Eastern Europe may come to command increasing attention, and eventually call for a resort to political instrumentalities of competition to partially compensate for the disequilibrium in the military equation: such instrumentalities in the form of political, diplomatic and related politics may then have to be called upon to play an increasing role in the growing East-West imbalance of power in Europe is to be redressed by other than military means.

From the geostrategic, economic, military and political standpoints, then, Eastern Europe is of great significance to the free world. It is a region of utmost importance to the security and freedom of Western Europe, and consequently to the security of the U.S. as well.

## THE WARSAW PACT

### *Introductory Observations*

The Treaty of Friendship, Cooperation and Mutual Assistance known as the Warsaw Pact was concluded on May 14, 1955 as a multilateral alliance treaty between the Soviet Union, East Germany, Poland, Czechoslovakia, Hungary, Romania, Bulgaria and Albania. Pursuant to the Pact's provisions, the Warsaw Treaty Organization (WTO) was established in the same year by the Pact's signatory states. (Albania withdrew from the Warsaw Pact and WTO de facto in 1961 and formally in 1968; Soviet reprisals were precluded by Albania's geopolitical position). The Warsaw Pact is due to expire in 1985, unless an all-European collective security system (for which "the contracting parties will unswervingly strive") is established, in which case the Warsaw Pact will expire from the moment the all-European security treaty enters into force (Art. 11). Failing this, the Warsaw Pact and the arrangements governing WTO will probably be renewed before their 1985 expiration date.

The applicability of the provisions of the Warsaw Pact is explicitly limited geographically to the European theater (Art. 4). However, as shall be seen below, the bilateral alliance treaties and military cooperation arrangements between the Soviet Union and individual East European states do not necessarily operate under this territorial restriction.

The signatory states of the Warsaw Pact are precluded from entering into other alliances (Art. 7). This constitutes a clear limitation to the independence of the East European states and an expression of the concept that they belong inseparably and exclusively to the Soviet alliance system, to which Soviet authority has not until now allowed any alternative.

The relationship of the East European states to the Soviet Union can not be defined in terms of an alliance or mutual security arrangement, or described as a coalition of states in the conventional sense.

of the term. This is not only because its members are so greatly overshadowed by the hegemonic power position of the USSR, and are dependent on it in all military areas (from strategic deterrence to air defense to virtually the full range of armaments) as well as for political support and guidance. In addition to these characteristic imbalances, what makes the Warsaw Pact historically unique as an alliance system is the fact that it is a grouping of ideologically kindred ruling parties as well as states, united by a mutually shared world outlook, intent upon defending, conserving and propagating a common concept of socio-economic organization and political rule, and committed to a set of ideological imperatives universalist in their nature.

The primary role of the Warsaw Pact system in its over two decades of existence has in practice been not to defend the national territories and independence of its members against external aggression, but to ultimately guarantee the East European Communist regimes against internal opposition. So far the only military operations undertaken by and/or in the name of the Warsaw Pact—principally by the Soviet Union—have been in the nature of intra-bloc police actions: the interventions in two member states, Hungary and Czechoslovakia, with the object of preserving the Communist Parties' monopoly of power.

#### *Political Functions of the Warsaw Pact*

It is no exaggeration to say that the military functions of the Warsaw Pact are far outweighed in importance by its political functions. Consequently, an examination of the Pact's significance should begin with the political rather than the military role played by it.

The Pact's political functions are of two orders: internal (intra-bloc) and external (international).

From the standpoint of intra-bloc relations, the Warsaw Pact constitutes a mechanism for strengthening political cohesion within the bloc and enforcing Soviet control over its members. It has also performed the role of a conflict-containing and conflict-resolving organism serving to maintain and legitimize the position of the Soviet Union as the supreme arbiter of Soviet bloc affairs. The Pact also represents a form of reinsurance both for Moscow, against possible independent-minded policies by national Communist leaderships, and for these leaderships themselves, against popular opposition to their rule. The Pact thus constitutes an instrument for the perpetuation of Soviet control over Eastern Europe through the Communist regimes in the region's states (although, as shall be seen below, not the only instrument and not even the most important one, but certainly the most effective among the multilateral institutions of the Soviet bloc). Moreover, the Warsaw Pact provides added legal justification for the stationing of Soviet troops in four of the six East European member countries of the alliance: German Democratic Republic, Poland, Czechoslovakia and Hungary, strategically located on the Central European front. The events of 1956 in Hungary and 1968 in Czechoslovakia have vividly demonstrated the extent of popular discontent with the presence of Soviet troops in the region and aspirations to disengage from the Soviet alliance system, as well as the high premium placed by Moscow on the continuation of its control and military presence in this forward base area. Clearly,

withdrawal from the Warsaw Pact or unilateral initiatives for Soviet troop removal by an East European country are unacceptable to Moscow. The Soviet military hegemony in Eastern Europe, symbolized by the Warsaw Pact, remains the ultimate guarantee of Soviet political domination of the area.

From the standpoint of international politics, the main functions of the Warsaw Pact are to be found in the realms of diplomacy and propaganda. The Pact has from its inception been, and continues to be, used as a bargaining chip and quid-pro-quo in Soviet proposals aimed at bringing about a negotiated end to NATO. In this respect the meetings of the Pact's Political Consultative Committee (see below) have over the years performed the role of sounding board for Soviet foreign policy positions, particularly for the airing of Soviet proposals with respect to European questions and European security schemes. Soviet propaganda has persistently promoted the idea of a mutual dissolution of the Warsaw Pact and of NATO (the Warsaw Pact Treaty in its Art. 11 makes specific provision for the dissolution of the Pact in the event of the conclusion an all-European collective security system and treaty, which this article as well as the preamble enjoin its signatories to assist in bringing about). The ongoing M(B)FR talks are illustrative of the Warsaw Pact's value as a bargaining lever for the Soviet Union in East-West negotiations.

In addition, the Warsaw Pact provides a guarantee for the maintenance of the territorial status quo in Central Europe, inasmuch as three of its members: German Democratic Republic, Poland and Czechoslovakia, derive from their membership the Pact's support, the former for its existence as a separate German state, the latter for retention of territories acquired from Germany at the end of World War II and whose status has yet to be legalized by a peace treaty (although some progress toward legal acceptance of these frontiers has been marked by the treaties concluded by West Germany with Poland, Czechoslovakia and the Soviet Union, and subsequently by the Helsinki accords).

The obverse of this function of conserving the status quo in the Eastern half of Europe is the Warsaw Pact's role in assisting in its incremental transformation in the continent's Western half. The forward deployment of Soviet and Warsaw Pact forces in Central Europe has the effect, to use George Kennan's term, of casting a "psychological shadow" which extends over Western Europe as well as over Eastern Europe. This situation can not, over the long run, fail to exert a certain degree of influence upon the domestic politics and foreign policies of the West European nations, probably with increasingly apparent results if the factor of geostrategic and political proximity continues to be compounded by the present trends in the East-West (strategic and naval as well as theater) balance of forces.

Finally, from the perspective of world politics, the Warsaw Pact and Soviet domination thereof elevates the Soviet Union to the position of leader of a group of powers and of one of the world's two competing alliance and political-ideological systems, thereby bestowing upon the Soviet Union the status and prestige attendant to that position, and placing Moscow on a level of symbolic equality with the United States as a rival alliance and system leader in the contemporary world.

*Military Functions of the Warsaw Pact*

From the military standpoint, the Warsaw Pact's functions can be broadly defined as providing the framework for military cooperation and coordination among the armed forces of the member states, and augmenting the Soviet Union's military capacities against the West.

The armed forces of the Warsaw Treaty Organization (WTO) have attained an advanced degree of coordination and standardization in the areas of planning, strategy, doctrine and training, through the generalized adoption and assimilation of Soviet concepts, objectives, methods and organizational forms. This achievement is chiefly due to the disproportionate weight carried by the Soviet Union and its hegemonic position—political as well as military—within the alliance, and has also been facilitated by the fact that considerable numbers of East European officers have undergone Soviet training.

An advanced degree of standardization of equipment has also been attained by the WTO forces, thanks mainly to the extensive Soviet supply programs over the past fifteen years, and in addition to the local manufacture by Warsaw Pact allies of selected categories of military materiel in accordance with Soviet and WTO common standards and specifications. Quite apart from its beneficial economic effects concerning production efficiency and costs, equipment standardization simplifies supply problems and ensures inter-allied weapons coordination, ammunition compatibility, inter-operability of equipment, and theater flexibility. WTO is far ahead of NATO with respect to equipment standardization, not having had to contend with the problems confronting the Atlantic Alliance in the form of dispersion of efforts and duplication of weapons arising from the existence of individual national arms industries with a multiplicity of standards and reflecting varying military doctrines. No WTO member state possess a national manufacturing capability for a complete range of military equipment. Successful standardization of WTO materiel is the result, however, not of production cooperation and specialization among members (with the partial exception of Czechoslovakia's specialized manufacture of reputable light arms for export within as well as outside the bloc), but of the general adoption of Soviet equipment standards and the perpetuation of a Soviet quasi-monopoly of manufacture and supply particularly with respect to military hardware and to more advanced weapons.

The bulk of the equipment in use in the WTO armed forces is also in use in the Soviet armed forces, although the proportion of up-to-date materiel in the former is lower than it is in the latter. Advanced conventional weapons systems from the Soviet inventory have increasingly been made available to the WTO armed forces (although time lags do occur between the Soviet deployment of a particular weapon and its delivery to WTO allies, due in some instances to priority deliveries to Moscow's Middle Eastern arms recipients). Such advanced items have included the T-62 (T-70) tank, the PT-76 amphibious tank, the Mig 21 plane, SAM 6 rockets, and anti-tank precision wire-guided weapons, as well as self-propelled artillery guns and amphibious personnel carriers. The Pact's members have also been equipped with Scud and Frog surface-to-surface missiles capable of carrying both conventional and nuclear warheads, but access to the nuclear warheads has remained strictly Soviet-controlled.

The main recipients of advanced types of Soviet weaponry have been the German Democratic Republic, Polish and Czechoslovak armed forces, situated on the Central European front. The expansion and extensive modernization and training programs of these forces in recent years reflects Moscow's increased reliance on the contribution of its allies to total WTO conventional military capacity and combat potential, particularly in view of the apparent Soviet conclusion (as it surfaces in Soviet military writings) that strategic nuclear parity tends to enhance the possibility of conventional regional conflict in Europe.

In addition to the forces of the Central European WTO members (whose aggregate levels are given in their principal components in a preceding section), Soviet forces stationed in the Central European area comprise thirty-one divisions (an increase of five divisions since 1968), including fifteen tank divisions, with their weaponry being continually upgraded.

The geostrategic and political importance of this area explains the concentrated Soviet and WTO efforts to steadily upgrade the theater forces stationed therein. The emphasis placed upon the expansion of military capabilities in this sector stands in contradistinction to the situation prevailing in the WTO's Balkan sector, consisting of Romania and Bulgaria, an area referred to as the "Southern tier" of the WTO and regarded as being of secondary strategic and political significance. In contrast, the "Northern tier" (German Democratic Republic, Poland and Czechoslovakia) is officially described as "the first strategic echelon" of the Warsaw Pact, and it is here that the Soviet Union and WTO have concentrated the effort to achieve significant military superiority. This forward base and deployment area holds decisive strategic and political importance both in terms of European and global power politics, opening as it does the way for direct Soviet action in or pressure upon Germany and Western Europe. The military capacities of the WTO forces of the "Northern tier" states have steadily increased in recent years and represent a significant accretion to the Soviet Union's own theater warfare potential and peacetime threat value in Europe.

#### *Formal Structure and Organization*

The two major coordinating and policy issuing bodies of the Warsaw Pact and WTO are the Pact's Political Consultative Committee (PCC) and the Joint Command of the WTO armed forces, both with headquarters in Moscow.

The PCC's main functions have to do with the general coordination of the foreign policy of the Pact and its member states and the airing of bloc positions on international, particularly European matters. The PCC consists of the General (or First) Secretaries of the Communist Parties, the Presidents of the Councils of Ministers and the Ministers of Foreign Affairs of the member states. The statutory frequency of PCC meetings is twice a year, although in practice their frequency has been varying over the years: while only eleven meetings (instead of thirty) took place between 1955-1969, the statutory requirement of biannual meetings has come close to being met in the years after 1970, reflecting the greater Soviet emphasis on the Pact's military value and increased Soviet politico-diplomatic activism in European affairs. Between PCC meetings routine business is carried out by the Permanent Commission and the Joint Secretariat, both of which are

located in Moscow and whose staffs are headed by and consist predominantly of Soviet representatives.

The Joint Command is the policy issuing and overseeing body for the Joint Armed Forces, whose Staff implements Joint Command decisions. Each WTO member state is represented on the Joint Command by a Deputy Defense Minister with the title of Deputy Commander in Chief of the Warsaw Pact armed forces. The Commander in Chief of the Warsaw Pact armed forces has always been a Soviet officer—currently Army General Viktor G. Kulikov—with another Soviet officer as First Deputy Commander in Chief—a post filled *ex officio* by the Chief of Staff of the Joint Armed Forces—and one Soviet Deputy Commander in Chief. (General Kulikov's predecessor, Marshal Ivan Y. Yakubovsky, died in November 1976. Like Yakubovsky, Kulikov is an armor officer and a former commander of the Soviet forces in the German Democratic Republic).

The Staff of the Joint Armed Forces has been institutionalized since 1969, after having previously been set up on an *ad hoc* basis in connection with the various joint maneuvers carried out during the 1960's. It is composed of Soviet and East European Deputy Chiefs of Staff, mostly of Major General rank (two Soviet and one for each East European state), assisted by national delegations whose size is proportionate to the military contribution of each state. The post of Chief of Staff of the Joint Armed Forces has always been occupied by a Soviet General—currently by Army General Anatoly I. Gribkov (he succeeded in April 1976 his deceased predecessor, General Sergei M. Shtemenko).

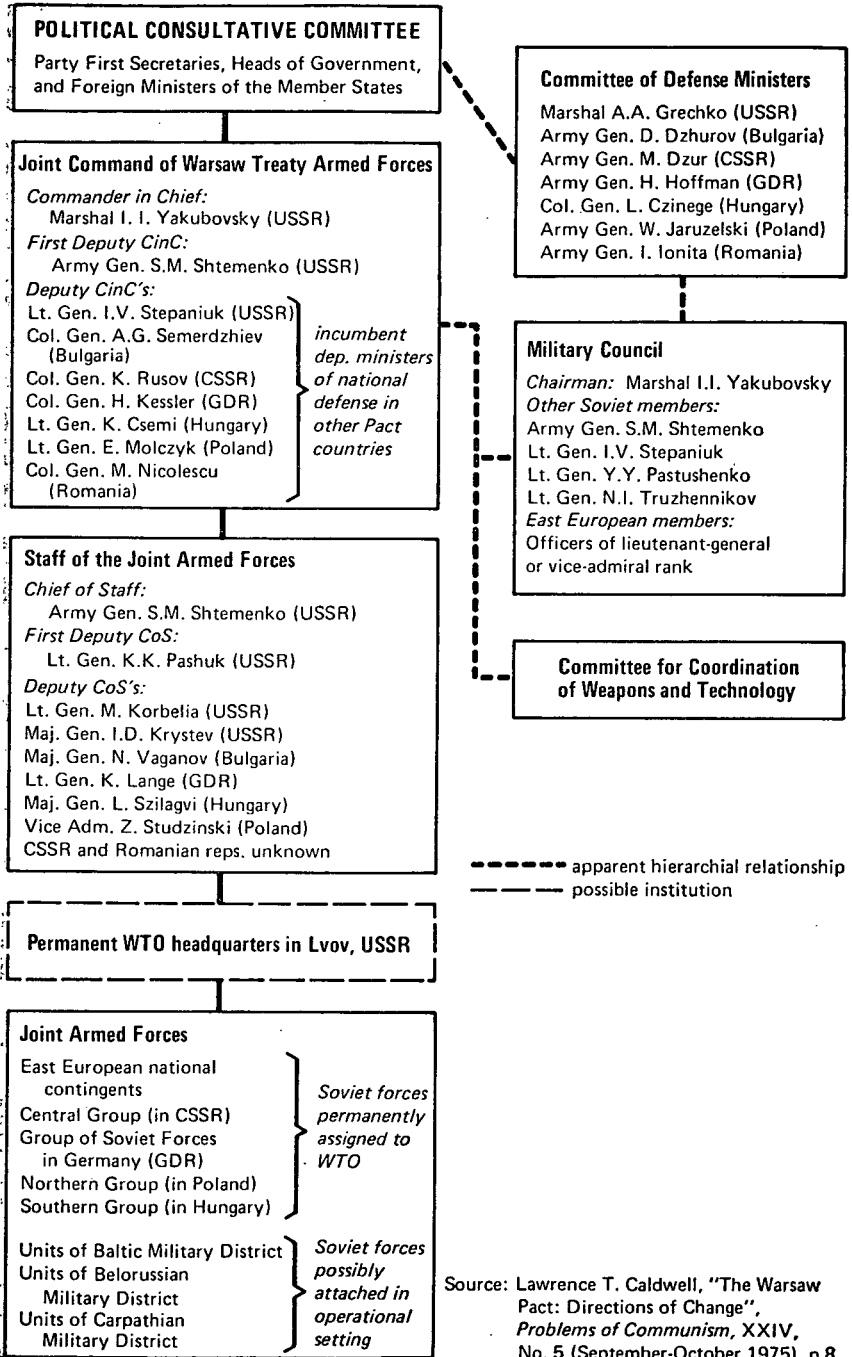

It is not clear what the attributions (officially referred to as "consultative") of two other WTO organs created in 1969 are. The first of these, the Committee of Defense Ministers (whose establishment formalized the long-standing practice of the Defense Ministers' multilateral meetings) does not appear to entail for its members any responsibilities beyond those of their respective national offices. Moreover, it is the Commander in Chief, not the Committee of Defense Ministers, who has the responsibility of advising the PCC on military matters. The second of these organs, the Military Council of the WTO, which is headed by the Commander in Chief of the Warsaw Pact armed forces and the Chief of Staff of the Joint Armed Forces and heavily dominated by Soviet officers, is likely to function as a consultative body patterned on the military councils of Soviet military regions and "fronts".<sup>3</sup>

Finally, one other relatively new organ instituted in 1969 and about whose functioning even less is known is the WTO's Committee for Coordination of Weapons and Technology.

While these WTO institutional bodies may create the appearance of a multinational political process in WTO policy formation and command structure, there is little doubt that actual decision-making and execution power, to the extent to which it is vested in WTO, is concentrated firmly in Soviet hands. However, WTO itself does not provide effective means for systematic policy-making and centralized enforcement of decisions. These are ensured by the Soviet Union's capacity in relation to each individual East European state to induce conformity with respect to the adoption and implementation of decisions that Moscow wishes to see carried out.

# WTO Command Structure

Source: Lawrence T. Caldwell, "The Warsaw Pact: Directions of Change", *Problems of Communism*, XXIV, No. 5 (September-October 1975), p.8.

*Bilateral Politico-Military Ties—The Substance of the Soviet-East European Alliance System*

It may be concluded from the above that the Soviet Union has avoided multinational military integration of the WTO member states, having clearly found it more convenient to control their respective armed forces separately (in ways which will be outlined below). Meaningful integration among the armed forces of the East European states on a multinational basis would be inconsistent with, and is precluded by, the complete Soviet domination of WTO and of the military establishments of each individual WTO state. Soviet hegemonic motives (quite apart from the muted nationalistic frictions persisting among the East Europeans themselves) thus account for the fact that cooperation among East European armed forces is extremely reduced, and that even at joint maneuvers there is only minimal contact between the various national units.

In peacetime the great bulk of the armed forces of the East European states remain subordinated to their national commands and under the control of the respective Communist Party leaderships. (The only exception to this rule are the East German armed forces, which are in their entirety under the authority of the WTO Joint Command and consequently under Soviet authority). The principle of national, i.e. Communist Party, control over the national armed forces in peacetime continues to be basic to the organization of WTO.

Removed from national authority in peacetime are only those units of the East European armed forces which, in accordance with Art. 5 of the Warsaw Pact, are "assigned" to the Joint Command. The Joint Armed Forces of WTO are mostly Soviet in composition: they consist of the Soviet forces stationed in East Germany, Poland Czechoslovakia and Hungary, all East German forces, and selected limited national contingents from the other WTO member states specially earmarked for WTO service. In various operational contexts Soviet forces stationed in the Soviet military regions abutting on the Soviet Union's Western frontiers would probably be attached to the Joint Armed Forces.

The East European contingents assigned to the Joint Armed Forces are ultimately subordinated to the Soviet high command: the commander of the Soviet Ground Forces commands the WTO Joint ground forces as well (Army General Ivan G. Pavlovsky, who directed the Soviet-led Warsaw Pact invasion of Czechoslovakia); the commander of the Soviet Air Forces also commands the WTO Joint air forces (Aviation Marshall Pavel S. Kutakhov); and the commander of the Soviet Navy, Fleet Admiral Sergei G. Gorshkov, also commands the WTO Joint naval forces (in the Baltic Sea the chain of command passes through the commander of the Soviet Baltic fleet, under whose authority are the Polish and East German fleets). In addition, the air defense forces of all East European states have been integrated under the authority of the commander of the Soviet air defense forces (Marshal Pavel F. Batitsky) who is concurrently the WTO commander of air defense forces.

All these command arrangements, along with the continued Soviet quasi-monopoly of the second and even third level command positions in WTO, are probably fair indications of the nature of operational arrangements under which the East European armed forces would

function in time of war. There is no indication that at such time the WTO and its institutional bodies would assume any meaningful functions. The type of integration apparently being envisaged for the WTO armed forces in time of war is their integration on a bilateral basis with relevant Soviet theater forces. There is consensus among military specialists that in case of military conflagration in Europe the armed forces of the East European states probably would not operate within the framework of WTO or be commanded through WTO, but would be incorporated directly in Soviet army groups and subordinated to the authority of the Soviet theater and high command. (Moreover, as part of Soviet "fronts" or army groups they would probably operate with Soviet forces on their flanks and rear to shore up their performance).

This pattern, which was employed by the Soviet Army in the closing stages of World War II, and is validated by contemporary Soviet military doctrine, was followed in the Soviet-led invasion of Czechoslovakia: while the WTO command under Marshal Yakubovsky was in charge of the pre-invasion WTO maneuvers in and around Czechoslovakia, the WTO invasion forces consisting of Soviet, East German, Polish, Hungarian and Bulgarian units were deployed by the Soviet field commanders without reference to WTO, and the whole operation was directed by General Ivan G. Pavlovsky, the Commander in Chief of the Soviet Ground Forces, from a forward headquarters of the Soviet high command. In short, WTO appears to be of little relevance to Soviet planning for theater war in Europe and without responsibilities for the conduct of military operations. Its main attributions, as Malcolm Mackintosh concludes, are primarily administrative in nature and pertain chiefly to mobilization, training and equipment.<sup>4</sup>

The absence of multilateral integration in WTO, the latter's military irrelevance in wartime, the often-reiterated Soviet offer to have WTO dissolved together with NATO (as well as, on a more general plane, the time-honored Soviet preference for the bilateral approach in its relationships of all kinds with the East European states), all these considerations lead to the conclusion that multilateral institutions and multilateral cooperation do not form the basis of the Soviet-East European alliance system.

The real and solid foundation and infrastructure of this system is the network of bilateral alliance treaties and other formal and informal ties and arrangements in existence between the Soviet Union and the states of Eastern Europe on a bilateral basis.

The long-term alliance treaties forming the legal base of this system were concluded by Moscow bilaterally with each bloc state, and also by each bloc state with each other one, before the establishment of the Warsaw Pact and WTO, were subsequently supplemented by status of forces agreements, and were renewed in recent years for periods of twenty to twenty-five years. They are likely to remain in force in the event of the achievement of the Soviet objective of a simultaneous disbandment of NATO and WTO.

The significance of these treaties and agreements is as follows. First, they define the politico-military relationship of the Soviet Union to each of its East European allies, and serve to formalize Soviet domina-

<sup>4</sup> Malcolm Mackintosh: "The Warsaw Pact Today," *Survival*, May-June 1974.

tion thereof. Second, they legalize the stationing of Soviet forces in four East European states. Third, they establish the basis for bilateral military cooperation in wartime, unavoidably under Soviet command. Fourth, they sanction in advance the use of the armed forces of any and all East European states in any area of the European theater, since the cumulative effect of the network of treaties is to extend and generalize the obligations of mutual assistance of each state so as to automatically commit all of them to a conflict involving any one of them. This latter effect of the Soviet-East European treaty network amounts cumulatively to a legal duplicate of the Warsaw Pact, and a substitute for it (ensuring, *inter alia*, continued forward deployment of Soviet forces in Central Europe) in the event of a negotiated simultaneous dissolution of WTO and NATO.

In addition, bilateral alliance treaties renewed in recent years between the Soviet Union and the East European states differ from the Warsaw Pact in that their language tends to extend geographically the obligation of military assistance by discarding the Pact's territorial limitation to Europe.

The presence of Soviet forces in the German Democratic Republic, Poland, Czechoslovakia and Hungary, with all its implications in terms of Soviet political domination and military control of these states (quite apart from the implications in terms of international politics), is governed not by WTO arrangements, but by bilateral arrangements between the Soviet Union and each country concerned. Troop disposition and movements are being arranged between the Soviet commanders and the respective state authorities, with the local Defense Minister probably providing the main contact between the Soviet command and the local political leadership. The stationing of Soviet forces in these countries is normalized by bilateral status-of-forces agreements which go to great lengths in emphasizing the sovereignty of the host state, and even make the dubious claim, as does the post-invasion agreement with Czechoslovakia, that the presence of Soviet forces "does not violate the sovereignty" of the country.<sup>5</sup>

An additional instrument of Soviet control outside WTO machinery is provided by the Soviet military missions in the East European capitals (which were also instituted before the establishment of the Warsaw Pact). In addition to their military training and advisory roles, these missions constitute a bilateral conduit for exerting Soviet influence and surveillance over the East European military establishments, cultivating pro-Soviet military interest groups, and maintaining a potential substitute for WTO mechanisms and channels in the event of a negotiated dissolution of military blocs.

Deliveries of Soviet equipment to the East European armed forces are likewise arranged on a bilateral basis, with the Soviet Union deriving the advantages in terms of political as well as military leverage accruing to a virtually unique supplier in relation to its client.

Soviet control over the military establishments of the East European states is exercised through nationals of these states as well. Former Soviet officers who adopted the citizenship of one or another East

<sup>5</sup> Yet another matter of bilateral arrangements between the Soviet Union and some East European countries is the delivery to the Soviet Union of probably their entire output of uranium, the amounts of which are not disclosed, from the uranium mines near Aue in the German Democratic Republic, at Jachy mov, Teplice and Pribam in Czechoslovakia, and near Pecs in Hungary. (Romania's Soviet exploited uranium reserves appear to have been exhausted in the early 1960's).

European state, or officers of Russian or Ukrainian background, are still occasionally to be found in prominent positions in East European armed forces, but their numbers have markedly declined in comparison with earlier periods. By now a considerable proportion of the officer corps, particularly of senior rank, in the East European military establishments have undergone Soviet training, and many of them have in all likelihood preserved Soviet connections and remained receptive to Soviet guidance or responsive to Soviet directions. All East European Defense Ministers have either received training in the Soviet Union, or have had careers as political commissars, or both.

Finally, the East European states, their military resources and their intelligence apparatuses have been individually utilized by the Soviet Union as intermediaries or proxies in its conflict undertakings abroad, outside the framework of the Warsaw Pact. Such assignments as intelligence operations, covert and subversive activities, delivery of arms to anti-Western governments, supply and training of guerrilla movements, or dispatch of instructors, have been performed by virtually every East European state on behalf of the Soviet Union, in most areas of the world beyond Europe, with no reference to the Warsaw Pact or WTO.

In conclusion, the substance of the Soviet-East European alliance system consists of an intricate web of politico-military ties, both direct and indirect, both formal and informal, which antedate the establishment of the Warsaw Pact and WTO, function to a large extent outside its framework, and will in all likelihood continue to function in the event of an East-West negotiated agreement for the mutual dismantling of military blocs.

#### GENERAL CONCLUSIONS

Eastern Europe as a region remains, as it has historically been, an object rather than a subject of international relations. At present the Soviet Union exercises undisputed politico-military control over Eastern Europe, and the West has long refrained from challenging it or from attempting to resume a political role in the region. Control over Eastern Europe strengthens substantially the Soviet power position in international politics in geopolitical, economic, and military terms. In the long run perhaps the chief importance of Eastern Europe to the Soviet Union is that it places the latter in an advantageous position to pursue the object of gradually neutralizing and eventually dominating Western Europe, the key to the world balance of power, and thereby achieving a sum of power which would give the Soviet Union a position of dominance in world politics.

The Soviet-East European alliance system provides the main guarantee for the continuation of Soviet authority in Eastern Europe. The way in which this system is organized and operates tends to substantiate the continued validity of the metaphoric description of the East European regimes' dependent position vis-à-vis the Soviet power center as satellites of the Soviet Union. The Communist regimes' domestic monopoly of power is derivative in nature, being a function of their external politico-military alignment with the Soviet Union.

The phenomena of political dissent and social unrest which have recently surfaced with new vigor in Eastern Europe are not in themselves likely to develop into processes of internal change with implications for the international system and the East-West power balance. For the foreseeable future, the Soviet-East European alliance system can be safely expected to continue to fulfill its "internal" political function of containing the latent political instability of the area. Meaningful internal change with consequences affecting international relations can not be achieved from within the region, as historical experience has repeatedly shown, unless external factors can be brought into play. The key to continuity or change in the political status of Eastern Europe and in its alignment in international relations lies outside the region itself.

## I. INTRODUCTION

The purpose of this overview is twofold. As coordinator of the nine country studies (two on Romania) which follow, my first task is to summarize, selectively highlight, and provide a guide to the contributions. My second purpose is to present some of the most important similarities and differences among the eight countries and to provide analytical insights on selected issues. The East European countries differ in most respects: size; resource endowment, historical and cultural experience, nationality, language, level of economic development, direction and speed of changes in their economic system, development strategy, economic performance, and political orientation. These countries would differ from one another even if Albania and Yugoslavia were not included; their inclusion increases the diversity.

The nine studies vary in coverage and length. This is partly deliberate and partly the result of circumstance. Coverage of the individual contributions has been determined in part by the availability of data and new information, and partly by the extent of analytical work already completed in the West. For countries such as Albania, Romania, and Bulgaria, much of the effort had to be devoted to collecting, evaluating, and presenting hitherto not readily available information and data. This is one reason why the longest contribution is on Albania. Very little is known in the West about the economy of that country due to a combination of its tiny size, self-imposed isolation, lack of published data, and scarcity of experts in the West. We are particularly pleased, therefore, to present probably the most comprehensive and detailed English-language contribution on post-war economic developments in Albania. Among the unique features of that country study are: (1) the reconstruction of Albania's national accounting framework; with estimates of components in Albanian currency and conversion of the main aggregates into U.S. dollars; (2) an economic comparison between Albania and the Albanian region of Yugoslavia, i.e., the autonomous province of Kosovo where two-fifths of the four million Albanians in the Balkan peninsula reside; and (3) detailed post-World War II estimates of Albania's aid and

trade relations, a notable contribution in view of the fact that neither China nor Albania publishes statistics on aid and that Albania has reported no trade figures since 1965.

The second longest contribution is on Romania, another country for which few comprehensive statistics are available in the West. Jackson's contribution represents an updating of information and data contained in Montias' *Economic Development in Communist Rumania*, which analyzed developments in that country up to the mid-1960's. Montias also contributes an essay, focusing on the relationship between the country's industrialization strategy and foreign trade performance.

For countries like Hungary, Poland, and Yugoslavia, which have already received analytical attention by Western economists, the contributions are generally more analytical or they focus selectively on issues. For example, Portes examines the evolution of Hungary's New Economic Mechanism, and Fallenbuchl discusses Poland's new economic strategy and its implications.

Contributions in other sections of this volume discuss particular issues all across Eastern Europe in much greater depth than was possible in the individual country studies or in this overview. These include such topics as economic structure and performance of six East European countries (excluding Yugoslavia and Albania) by Alton, a cross-section contribution on East European agriculture (including Yugoslavia) by Lazarcik, on economic reforms in Eastern Europe by Bornstein, and others focusing on energy, trade, and the balance of payments.

Part II of this essay calls attention to some important "environmental" differences among the East European countries. The roots of the diversity in the region can be traced to the enormous differences in the initial postwar "environments" under which the centrally planned economic system was introduced in the East European countries. These differences were, in some cases, further accentuated, or diminished, by certain postwar events and the special economic links that some East European countries were able to forge with countries outside the region, such as Bulgaria with the USSR, Albania with China, and the GDR with the FRG.

Part III compares two of the most commonly used measures of economic growth performance, the officially reported NMP and Western-recalculated GNP figures for the period 1965-76 and plans for 1976-80. Each country is "ranked" on the basis of these indicators. It must be stressed, however, that the statistical measures are not yet precise enough to make fine distinctions among the countries. Hence, no great significance should be attached to relatively small differences in the performance indicators. Still, the tabulated data offer evidence on the relatively fast-growing and relatively slowly-growing countries in the region. Of particular interest is the attempt to place Albania and Yugoslavia in the East European spectrum. The recent growth performance of the two countries is neither particularly rapid nor especially laggard.

Part IV compares the sources of growth in Eastern Europe. Section A focuses on capital and labor inputs and productivity, but the available data are not good enough to draw more than a few highly tentative conclusions on the relationship between inputs and output. A brief country review illustrates many of the frustrating data problems.

More detail is presented on two other (and increasingly important positive or negative) sources of growth: Foreign borrowing and lending (Section B) and changes in the terms of trade (Section C). Three subsections examine (1) borrowing from the West; (2) credit relations with the USSR; and (3) credits granted by East Europe to less developed countries. In discussing East Europe's borrowing from the West and Albania's from China, the focus is on the growth contribution of borrowed resources rather than on the debt burden which borrowing creates.

In discussing East Europe's credit relations with the USSR, attention is drawn to the complexity of the relationship, stressing the two-way flow, not only of trade but also of credits. For a variety of economic and political reasons, individual East European countries are treated differently by the USSR so that no easy generalizations about the effect on their growth are possible.

In discussing the terms of trade, I attempted to go beyond readily available information in the individual contributions. Based on price information pieced together from a variety of sources, an estimate is made of the terms of trade since 1970 of all East European countries, separately with socialist and Western partners. For Hungary only, two price indices are presented in socialist and in Western trade: one set includes "dollar trade" with CMEA countries in socialist trade; the other excludes "dollar trade" from ruble-settlement accounts. The derivation of Hungary's 1975 "dollar trade" with socialist countries is found in the Appendix.

Section D highlights Keren's analytical conclusions on one country, East Germany, which shows how numerous pressures generated by the foreign sector are now converging on the GDR. It is suggested that the kind of analysis Keren presents may be applied to other East European countries if one seeks a better understanding of their prospects to 1980.

Part V highlights major differences and changes among the countries in their economic strategies, systems (reforms), and policies. The region is divided into the four Southern Tier (Balkan) countries and the four Northern Tier countries.

Part VI makes a few general observations about these countries economic prospects until 1980. The principal problems facing these countries are: (1) how to start repaying their hard-currency debts without seriously impeding the continued progress of their economies, and (2) the related problem of how to solve the systemic limitations on improving productivity. The latter issue is becoming more urgent because capital and labor inputs will grow much more slowly in the future.

## II. THE ENVIRONMENTAL VARIABLES

A country's economic strategy and performance is the outcome of many complex forces which can be classified into three broad groups of explanatory variables: environmental, systemic, and policy-derived.<sup>1</sup>

Environmental variables can be subdivided into those shaping the initial and those conditioning the contemporary environment. The division is to a degree arbitrary. It depends in part on the period

<sup>1</sup> Based on J. M. Montias' contribution to this volume and on E. Neuberger and J. Duffy, "Comparative Economic Systems" (Boston, Mass: Allyn and Bacon, Inc., 1975).

chosen for analysis: the policies and system features of one period shape the initial environment of the next period.

A useful point of departure for analyzing East Europe's contemporary achievements and problems is a brief examination of the initial environments in which these countries entered socialist economic construction after World War II because even today these inevitably condition their policies, performance and prospects. One of the most important general considerations across all of Eastern Europe at that time was the economic backwardness of much of the region. This could be measured by decades in the case of some countries; in the case of others, like Albania, perhaps by a century or more, as compared with the development levels and economic potential of the principal countries of West Europe. The writings of East European economists continually stress this point:

One of the most important criteria of survival of the new societies in Eastern Europe was their ability to close rapidly the large gap in the existing production and consumption levels as compared with the highly developed capitalist world, . . . dictated [in part] by the practical circumstance that these . . . countries were all located on the periphery of the capitalist world economy center: Western Europe.<sup>2</sup>

### *A. Different Initial Conditions*

East European countries introduced central planning under different initial conditions. Among the most important differences were the following:

#### SIZE OF THE ECONOMIES

Most striking of course is the difference between the relatively small and resource-poor countries of Eastern Europe and the continental-size and resource-rich USSR (whose economic model was inappropriately copied after the War in all East European countries). The East European economies ranged from tiny Albania to medium-size countries—in terms of population and land area—like Poland, Romania and the GDR.

#### LEVEL OF DEVELOPMENT

When World War II ended, the region could be divided into industrialized nations (the GDR and Czechoslovakia); countries at the beginning stage of industrialization, but with few developed industrial sectors (Hungary and Poland); and very poor, essentially agricultural societies (Romania, Bulgaria, Yugoslavia and, the poorest country by far in all of Europe, Albania).

#### STATEHOOD

In judging initial environmental conditions, one must consider how long ago the nation-state was created. A political unit whose territory had not been reorganized recently, with a history of effectively functioning governments in a stable nation-state, provides a much more solid base for economic development than a unit where these conditions were largely absent. With respect to territorial integrity, only two East European countries, Bulgaria and Albania, have been located essentially on the same territory since before World War I. The

<sup>2</sup> K. Pécsi, et. al., "Az európai szocialista országok gazdasága" (Budapest: Kossuth, 1975), p. 6.

nation-states corresponding to today's Hungary, Czechoslovakia, Yugoslavia, and Romania were formed only after World War I. By contrast, Poland was transformed after World War II with respect to its geography and the composition of its population; and the GDR was formed as a nation-state in the late 1940s, and then stood diplomatically isolated for about two decades by much of the Western world.

#### REGIONAL DISPARITIES AND NATIONALITY PROBLEMS

Many economic difficulties regarding the mobilization and allocation of resources may be avoided if a country has (1) no sharp conflicts among the different nationalities or other minorities that might live within its borders and (2) no serious regional inequality problems. In both respects, Yugoslavia was (and still is) the most heterogenous; significant differences also existed (and still do) in Czechoslovakia. The situation is more favorable in this regard in the other countries; although in Romania, 13% of the population is comprised of nationalities (9% of which are Hungarians). In Bulgaria, at least 10% of the population are Turks, Greeks, Romanians, Armenians, and so on. The other East European countries, with the exception of the GDR, also have minority national groups and relatively backward regions.

#### RESOURCE ENDOWMENT

The natural resource endowment of a country is an important environmental factor. This inevitably influences economic structure, industrial location, investment policy, and foreign economic relations. Possessing some natural resources that are important for the domestic economy and may provide significant export earnings are Poland (black and brown coal, copper, sulfur, lead, zinc, iron ore, aluminum, and natural gas); Romania (oil and gas, coal, bauxite and salt); Yugoslavia (iron ore, copper, timber, lead, coal, bauxite); and Albania (chromium, timber, bitumen, lignite, crude oil, gas, copper and iron ore). Poorly endowed with natural resources are the GDR (although it has brown coal, potash, iron ore); Czechoslovakia (coal, antimony, magnesite, pyrite, fluorspar, iron ore, copper, manganese); Hungary (bauxite, coal, natural gas, sulfur); and Bulgaria (low-grade coal, lead, zinc, copper, chromium, manganese ore, asbestos).

An important aspect of resource endowment is the suitability of the country's soil and climate for agriculture. Quite well endowed in this respect are Hungary, Romania, Bulgaria (reasonably self-sufficient in food and some possible net exports) and, to a lesser extent, Poland and Yugoslavia. The GDR and Czechoslovakia are more suitable for industrial specialization.

Location and climate are also important for attracting tourists who tend to seek sun and water. Yugoslavia, Bulgaria, Romania, and, to a lesser extent, Hungary have exploited this advantage since the mid-1960s by specializing in providing tourist services, while Albania has not yet taken advantage of its tourist potential.<sup>3</sup>

<sup>3</sup> For a discussion of the economics of tourism in Eastern Europe, see Paul Marer and John Tilley, "Tourism," in "Reorientation and Commercial Relations of the Economies of Eastern Europe." A compendium of papers submitted to the Joint Economic Committee, Congress of the U.S. (Washington, D.C.: GPO, 1974).

## LOCATION

An important environmental condition is whether a country is landlocked, like Hungary and Czechoslovakia, or has a long seashore and good seaports, like the GDR, Poland, and Yugoslavia.

## WAR DAMAGE, REPARATIONS, AND OTHER UNREQUITED TRANSFERS

The war had different effects on the countries of Eastern Europe in terms of the destruction of physical and human capital as well as postwar reparation obligations. In terms of war-related destruction, the greatest damage was suffered by the territory which subsequently became the GDR, and Poland, whose capital and other cities were largely destroyed. Reparations were made principally to the USSR, along with outright economic exploitation by the Soviets under Stalin. The GDR carried the largest burden by far, but substantial economic resources were also extracted from several other East European countries. My own rough estimate, based on careful assessment but rather incomplete data, suggests that until Stalin's death in 1953, the size of the unrequited flow of resources from Eastern Europe to the Soviet Union was of the same order of magnitude, cca. \$14 billion, as the flow of resources from the United States to West Europe under the Marshall Plan.<sup>4</sup>

## NO TRADITION OF REGIONAL COOPERATION

Isolated by the USSR and the West from much of the outside world after World War II, the region was without a historical tradition of regionwide economic or political cooperation. In addition to the obvious problems posed for these countries by Soviet domination, the lack of previous experience in regional cooperation made it that much more difficult to adjust to the new conditions. To be sure, the Soviet Union under Stalin discouraged economic and political cooperation among the East European countries. But even after this Soviet pressure ceased, intra-East European cooperation can be observed more in form than in substance; the lack of a tradition of regional cooperation is certainly a factor.

*B. Further Differentiation: Special Postwar Events and Status*

## OWNERSHIP PATTERNS IN AGRICULTURE

There is a striking difference among the East European countries, first, in the different emphases with which the postwar land reforms had been carried out,<sup>5</sup> and, second, after the initial collectivization drives began, in eventual decisions to permit the private sector to remain dominant (Poland and Yugoslavia) or to transfer agriculture into predominantly socialized forms (all other countries). To be sure, even among the latter there are significant differences in the relative importance of the residual private sector.

<sup>4</sup> Paul Marer, "Soviet Economic Policy in Eastern Europe" in *Reorientation*.

<sup>5</sup> In Czechoslovakia and Poland it consisted mainly of taking over former German and other "enemy" lands; in Hungary and Albania it liquidated feudal remnants of all types. In the other countries only a small portion of land was redistributed. See Nicolas Spulber, *Socialist Management and Planning* (Bloomington: Indiana University Press, 1971), Chapter 5.

The countries also differ in the form under which socialized agriculture functions. State farms are relatively the most important in Romania and Czechoslovakia (tilling approximately one-third of the arable land) and are least important in the GDR and Bulgaria. Moreover, collective farms vary with respect to size, organization, system of incentives and remuneration, to mention just a few of the factors that describe them. There are also significant differences among the countries, and in a given country over time, in the scope of activity permitted on private plots.

#### MILITARY BURDENS

East European countries differ in the size of their military expenditures which they decided, or have been asked to shoulder. It is generally believed that during the 1950s Czechoslovakia carried a particularly onerous burden.<sup>6</sup> During much of its postwar history, Yugoslavia also allocated a relatively large slice of its resources to national defense.<sup>7</sup> Even today, under conditions of relative peace, the burden of defense expenditures varies considerably from country to country.<sup>8</sup>

#### DRAMATIC EVENTS

Significant economic and political events have served as important backdrops to economic policy: the 1949–52 embargo of Yugoslavia by the Soviet Union and the other East European countries; the Western trade discrimination vis-a-vis Eastern Europe; the 1956 revolution in Hungary; the erection of the Berlin Wall in 1961 to stem the large outflow of professionals and skilled labor (between 1949 and 1961 more than 2 million residents—over 10 percent of the population—emigrated to West Germany); the 1968 Soviet invasion of Czechoslovakia; the 1956 upheavals and the 1970 and 1976 resistance to retail price rises in Poland; and the nearly 100% political and economic realignment of Albania during the early 1960s. There were also some dramatic natural disasters: the 1963 earthquake in Yugoslavia and the 1970 flood and 1977 earthquake in Romania.

#### SPECIAL LINKS WITH PARTICULAR COUNTRIES

Among the environmental considerations which bring significant economic benefits to one country but much smaller benefits or none at all to the others, are the special political and economic links that exist between countries.

#### *Bulgaria and the USSR*

The Soviets have given substantial aid in various forms to Bulgaria. For example, the Soviet Union gave several large, long-term, subsidized credits at an average interest charge of 2 percent—some

<sup>6</sup> R. Olsovsky and V. Prucha, eds. "Strucny hospodarsky vyvo Ceskoslovenska do roku 1955" (Prague: Svoboda, 1969), p. 397, as cited by Holesovsky.

<sup>7</sup> According to a Hungarian source, 17% to 18% of Yugoslavia's national income was devoted to national defense. K. Pécsi, "Az europai," p. 436.

<sup>8</sup> See T. P. Alton, et. al., "Defense Expenditures in Eastern Europe, 1965–1976," in this volume.

in hard currency—totaling 2.3 billion rubles by 1970.<sup>9</sup> The bulk of these loans are to be repaid with products of industrial complexes newly-established with the aid of these credits.

*Albania and the rest of Eastern Europe and China*

Until 1961, the Soviet Union and all other European socialist countries gave large, subsidized credits and other forms of aid to Albania. According to the careful compilation by Michael Kaser, economic aid by the USSR totaled \$156 million and technical and military assistance approximately \$100 million, while East Europe (excluding Yugoslavia) provided \$133 million in economic aid.<sup>10</sup> (Yugoslavia aided Albania only during 1947-49, when a confederation between the two countries was planned.)

It is interesting to compare the figures compiled by Kaser with data presented in a recent Hungarian publication.<sup>11</sup> It cites that in April 1957, the Soviet Union forgave Albania's cumulative debts of 442 million rubles (\$110 million) and granted further credits as follows: 1957: 160 million rubles (\$40 million); 1958: 31 million rubles (\$8 million); 1959: 339 million rubles (\$85 million). The East European countries granted and forgave subsidized credits to Albania up to 1961 as follows (in million rubles):

Creditor	Credits	Debt forgiven
Bulgaria.....	12.0	
Czechoslovakia.....	56.4	22
German Democratic Republic.....	22.9	14
Hungary.....	24.1	
Poland.....	18.9	
Romania.....	22.5	
Total.....	156.8	36
Amount (millions).....	(\$39.2)	(\$9)

The same publication also notes that in working out the details of the 1961-65 Third Five Year Plan, Albania still counted on receiving further credits, totaling 123 million rubles (\$31 million), from the socialist countries. But only a fraction of the credits had actually been extended before the break between the European socialist countries and Albania.

<sup>9</sup> K. Pécsi, "Az europai," p. 388. The figure cited is probably in "old" rubles, in which case it converts into \$575 million. Pécsi also mentions that Soviet deliveries to Bulgaria have always fitted exactly the requirements of the rapidly developing Bulgarian economy. No similar statement is made in discussing Soviet economic relations with the other East European countries.

Western calculations confirm the privileged economic position of Bulgaria. For example, from 1960 to 1965, she received almost as much aid as the other five East European client states combined, suggesting that economic aid has been a reward for political loyalty. C. Clark and R. Farlow, "Comparative Patterns of Foreign Policy and Trade: The Communist Balkans in International Politics" (Bloomington, IN: International Development Institute, Indiana University, 1976), Chapters 7 and 8.

<sup>10</sup> See contribution in this volume on Albania, Section V, Table V-3.

<sup>11</sup> K. Pécsi, "Az europai," pp. 490-492.

	<i>Million rubles</i>
Union of Soviet Socialist Republics.....	67.5
Czechoslovakia.....	24.8
GDR.....	9.0
Poland.....	2.3
Romania.....	6.8
Other countries.....	12.6
<b>Total.....</b>	<b>123.0</b>

<sup>1</sup> \$31,000,000.

In addition, other forms of aid were also given: hundreds of Albanian students studied and workers were trained in Eastern Europe; and these countries also sent engineers and other experts to Albania.

Since not all credits pledged after 1959 were fully used, the Kaser and Hungarian estimates on aid to Albania by the USSR are in close agreement. But it is interesting to note that the aid by East European countries itemized in the Hungarian source is significantly smaller than the figure cited by Kaser, although it is certainly possible that the Hungarian compiler was not aware of all the aid activity by the socialist countries.

After 1959, the principal donor of course became China, cumulating, on Kaser's estimate, \$838 million in aid by 1975.

#### *GDR and the Federal Republic of Germany*

Under a protocol of the 1957 Rome treaty which established the European Economic Community (EEC), West Germany's trade with East Germany was classified as "intra-German" and was therefore exempt from tariffs and levies which fall on trade with other non-EEC countries. Biskup quantified the benefits East Germany derives from this arrangement and concluded that a conservative estimate of its total gain in 1970 was more than DM 500 million (\$140 million at the 1970 exchange rates). It was comprised of the following items (estimated value to the GDR shown in parentheses):<sup>12</sup>

Tariff exemption for East German exports to West Germany (DM 260 m);

Exemption from levies raised on agricultural imports from all other non-EEC countries (DM 86 m);

Extra scope for price increases allowed by special arrangements for value added tax (DM 162 m);

Savings on interest payments owing to the interest-free swing credit provided by West Germany to finance trade between the two countries (DM 40 m); and

A fixed exchange rate between the two German currencies which has left East Germany unaffected by the D-mark's recent revaluations (effect not quantified).

Since intra-German trade has almost doubled since 1970, even if the benefit to the GDR has not risen proportionately to trade, its gain from this special relationship is undeniably substantial.

It is not possible at this stage of our knowledge to relate the special environmental factors listed for all countries directly to economic performance. Yet, one must state the obvious: the special factors mentioned above, the numerous other ones that surely were neglected, as well as the systemic differences among these countries must all be

<sup>12</sup> Reinhold Biskup, "Deutschlands offene Handelsgrenze" (Ullstein, 1976).

taken into account when performance is analyzed comparatively within Eastern Europe or the performance of the East European countries is compared with those of countries outside the region.

### III. ECONOMIC GROWTH PERFORMANCE

#### A. *Measurement Problems*

Growth rates depicting the output of the economy and its various sectors are published in greater or lesser detail by the central statistical offices of all East European countries. The growth rates officially claimed to have been achieved or planned show from moderate to spectacular results, depending on the country, economic sector, and period. Western experts consider the figures to be somewhat exaggerated because they are based on reports by enterprises subject, except in Hungary, to extraordinary pressures to fulfill the plan. The gross output indices sum the value of output of all producing units, and therefore include much double counting of inputs. If output in a given year is produced under more specialized arrangements than in a previous year—that is, involving a greater number of enterprises—the indices will be upward biased. A further bias is caused by a reporting system which permits and encourages the pricing of “new” products so that the value of gross output is artificially increased. The exaggeration varies not only from country to country and sector to sector but also from year to year. As a rule, the comprehensiveness of the published official statistics tends to be inversely related to the level of development (the GDR is a notable exception). The upward bias is believed to be the greatest in the official statistics published by the less developed countries, although the statistics of even the more developed countries are not immune from this problem, as is demonstrated by Keren in his contribution on the GDR, in this volume.

Western recomputations of East European growth rates employ definitions, methodologies, and weigh the component series in accord with standard Western approaches; but of course, they must contend with the scarcity of published data. Recalculated production indices by sector are based largely on officially published output series in physical units, an approach that may have a conservative bias because data in physical units do not reflect model changes and other quality improvements over time. This method also incorporates new products in the index with a certain lag after these products had been introduced. Still, most Western experts believe that the recalculated series are better indicators than the official series of long-term economic growth trends.<sup>13</sup>

#### B. *Findings*

A comparison of the officially published and recalculated Western aggregate output series (GNP or NMP) is presented in Table 1 for each of the eight East European countries as available, for subperiods between 1965–75 and annually for 1971–76. Available plan figures are also shown for 1977 and 1976–80. The tabulation includes data for Yugoslavia and the scattered series available for Albania, countries that are not part of the East European group analyzed in most statistical or analytical cross-section studies in this volume.

<sup>13</sup> Edwin M. Snell, “East European Economies Between the Soviets and the Capitalists” in Part I, pp. 12–53.

<sup>1</sup> Social product defined according to the material product approach (see L. Tyson's essay in this volume, footnote 19).

\* Not available.

† Preliminary.

Source: Bulgaria through Romania and Albania, Net Material Product (National income produced),

1965-76 and 1976-80 plan: United Nations Secretariat, Center for Development Planning, Projections and Policies, based on national plans and plan fulfillment reports (unpublished manuscript); Yugoslavia: Tyson's essay, tables 2 and 8; gross national product (recalculated Western series): Thad P. Alton, "Comparative Structure and Growth of Economic Activity in Eastern Europe" (1965-70 and 1970-75 average annual growth rates, calculated by least-squares fit, as shown in table 18, and 1971-76 annual growth rates calculated from index numbers presented in table 13).

The official NMP figures measure, in constant prices, gross output by sector less material costs, excluding the so-called non-material service sectors. The recalculated GNP figures measure aggregate economic activity, including the service sectors, by summing indices of sectoral output in constant prices, using factor cost weights. Because NMP and GNP differ in coverage, methodology, and bases of valuation, the two series are not expected to present the same picture on performance. The official NMP series, while upward biased, is believed to be one of the most important indicators used by the leadership in the East European countries to judge their own economic performance. The recalculated GNP series is our best estimate of how rapidly the East European economies are growing.

Methods of calculating the indices, the definitions used, as well as the many problems and pitfalls of making inter-temporal and international comparisons are stressed in the country studies which follow this essay and in the statistical cross-section studies presented elsewhere in this volume.<sup>14</sup>

#### RANKING THE COUNTRIES

Table 2 ranks the eight countries on the basis of their overall growth performance during 1970-75 according to official data. The ranking remains pretty much the same on the basis of GNP data (recalculated growth rates are not available for Yugoslavia and Albania), but would change slightly if 1965-75 growth rates were the criterion.

TABLE 2.—RANKING OF THE EAST EUROPEAN COUNTRIES BY GROWTH PERFORMANCE, 1965-76 ACTUAL AND 1976-80 PLAN

[Average annual rate of growth in percent]

Country and measure	1965-70	1970-75	1976	1977 plan	1976-80 plan
1. Romania:					
NMP .....	7.7	11.3	10.5	11.3	10.5
GNP .....	4.5	6.1	7.1	-----	-----
2. Poland:

<sup>1</sup> Not available.

Source: Table 1.

Based on 1970-75 performance, the eight countries can be divided into two groups; the three relatively fast-growing countries of Romania, Poland, and Bulgaria, and the less rapidly growing other countries. Taking the 1965-76 actual and 1976-80 plan figures into

<sup>14</sup> See especially the contribution by Thad P. Alton "Comparative Structure and Growth of Economic Activity in Eastern Europe," in this volume.

account, Romania can probably claim the first place and Bulgaria second.

Interesting to note is the position of Yugoslavia and Albania. Yugoslavia places right in the middle, during 1965-76 performing about the same as Hungary. During 1965-70 Albania claims to have grown roughly on a par with Romania and Bulgaria, but its growth slowed during 1970-75 and its performance was roughly on par with that of Hungary. To be sure, Albania's exceptionally poor and incomplete statistics and the absence of a Western recalculation undermines our confidence in the data and makes it particularly difficult to compare its performance with those of other countries.

#### PER CAPITA GROWTH PERFORMANCE

Population growth figures are presented in Table 3. The eight East European countries divide into four groups. At one end of the spectrum stands Albania where the annual population increment is about 2.5 percent—an extremely high rate even by world standards—reducing Albania's growth rates on a per capita basis by at least 1.5 percent vis-a-vis every other East European country. At the other end is East Germany, whose population continues to decline by about one-quarter of one percent per annum, raising its per capita performance slightly. Registering small population increases (in the one-third to two-thirds of one percent per annum range) are Bulgaria, Czechoslovakia, and Hungary. In the one percent per annum growth range are Romania, Poland, and Yugoslavia.

TABLE 3.—INDEX OF POPULATION GROWTH IN THE EAST EUROPEAN COUNTRIES, 1960-76

(Average annual percent change)

Period	Bulgaria	Czechoslovakia	GDR	Hungary	Poland	Romania	Yugoslavia	Albania
1965-70	0.70	0.28	0.04	0.36	0.80	1.28	1.04	2.80
1970-75	.56	.65	-.24	.39	.91	1.00	1.95	2.50
1975-76	.38	.86	-.30	.48	.92	1.00	1.95	2.50

<sup>1</sup> 1970-74.

<sup>2</sup> 1970-73.

\* Assumed to be the same as 1970-74.

† Assumed to be the same as 1970-73.

Source: Bulgaria through Romania, 1965-70: Paul F. Myers, "Population and Labor Force in Eastern Europe," in Reorientation, table 1; 1970-75 and 1976: T. P. Alton, "Comparative Structure \* \* \*," table 1; Yugoslavia: Statisticki Godisnjak jugoslavije" (Belgrade), various annual issues; Albania: compound growth rates calculated on the basis of population data presented in contribution in this volume by M. Kaser and A. Schnytzer, pt. 1, table 1-4.

Comparing growth performance in the 1970s on a per capita basis and taking into account plan projections to 1980 would change the relative position of Albania, moving it down among the relatively slow-growing countries; and of the GDR, moving it slightly ahead of Czechoslovakia on the NMP, and also of Hungary, on GNP basis.

#### IV. SOURCES OF GROWTH

##### A. Capital and Labor Inputs and Productivity

Attempting to make some statistically reasonable comparisons among countries on how much of their growth—and differences in their rates of growth—might be explained by differences in the growth

of factor inputs—labor and capital—and productivity has been an exercise in frustration. Our frustration, caused by practically insurmountable statistical difficulties, deepened when we attempted to comparatively identify the sources of growth of inputs. In the case of employment, growth can come from demographic factors, changes in participation rates, shifting labor from less productive to more productive sectors (principally from agriculture to industry) and a net inflow across national borders.<sup>15</sup> In the case of capital, growth can come from domestic sources—the crucial variables being the size of the existing capital stock, the share of national income devoted to accumulation, and depreciation—or net foreign borrowing.

Little systematic statistical information of this sort is available for Albania. For most other countries, not enough detailed statistics are available to disaggregate the data into their needed components. Even countries that publish detailed data have gaps in coverage and poor quality data. Moreover, the definitions and methodologies of calculation are not standardized among the countries, so that in most cases meaningful statistical comparisons cannot be made. This is why, even for a given country, alternative estimates often differ widely, depending on the (often unstated) definitions, the relative prices used as weights, and so on.

The greatest difficulty arises when estimating capital inputs; but even simple labor statistics are not immune from inconsistencies and comparability problems.

These caveats notwithstanding, the following broad generalizations seem to emerge from the available statistics.<sup>16</sup>

1. Increase in total employment since 1960 has been under 2 percent per annum in every East European country in each 5-year period, except as noted below; hence, employment growth has not been a dominant growth factor in most countries. The exceptions are:

(a) Poland, where total employment has increased by 2 percent or more since 1960, arising from a combination of demographic factors, increased participation rates in agriculture, and the movement of younger people from agriculture to industry and construction;

(b) Albania, for which no information is available, but fast employment growth can be deduced from the exceptionally rapid increase in population (Table 3) and the rapid rise in the labor participation rates of women, mentioned by Kaser and Schnytzer in their study in this volume; and

(c) Yugoslavia, where during 1971-75, a combination of the rapid increase in the labor supply and government policy had created substantial new domestic employment. This recent situation contrasts with the 1965-70 period when labor supply also increased rapidly (by about 5 percent per annum) but employment in the social sector grew by less than 1 percent per year. This caused a large number of Yugoslavs to seek employment outside the country (emigration provided twice as many new jobs as domestic employment) or become unemployed.<sup>17</sup>

<sup>15</sup> On the last point, see F. Levcik, "Migration and Employment of Foreign Workers in the COMECON Countries and Their Problems," in this volume.

<sup>16</sup> In addition to the individual country studies, the reader is referred to T. P. Alton, "Comparative Structure," Table 22 on labor inputs, Table 21 on capital inputs, and Table 5 on accumulation as percent of distributed national income.

<sup>17</sup> L. Tyson's contribution in this volume, pp. 941-996.

2. In all countries achieving a high rate of growth of output, industrial employment increased rapidly, in many cases between 3 and 6 percent per annum. Much of the increase was provided by declining agricultural employment.<sup>18</sup>

3. In all countries achieving a high growth of output, accumulation as percent of distributed national income (DNI) was high, rising to 30 percent or more by the early 1970's, or sooner. In the relatively slow-growing countries, accumulation as percent of DNI remained below 30 percent. The lowest share was revealed by the GDR, which needs to maintain consumption growth because of the politically sensitive competitive pressure it faces from West Germany in this regard.

It must be stressed, however, that comparisons of national income shares devoted to accumulation vs. consumption are notoriously problematic. Each country-study author approached the data problems and the analysis of growth sources differently.<sup>19</sup>

For Romania, Jackson provides a particularly good discussion of the difficulties of identifying the amount, share, and sources of investment in that country (see his Tables 7 through 11 and the related text discussion). He concludes that the high rates of growth achieved in the 1970s were based on a rapid growth of capital—made possible by holding down domestic consumption—and large transfers of labor from agriculture to industry.

For Bulgaria, Allen offers an interesting analysis by plan periods since 1948 of how various factors of production contributed to growth in the "nonagricultural sectors of material production." He attempts to separate out sources of extensive growth—growth in factor inputs and reallocation of these inputs from less to more productive sectors—and intensive growth—increase in productivity (see his Section 2). Because his analysis is based on a particular definition of the economy, data are not directly comparable with those presented by Alton in his (previously cited) contribution. Allen concludes that there has been a gradual shift from extensive to intensive application of labor, while at the same time the productivity of capital has steadily declined. Since 1960, two-thirds of the increase in capital stock has been devoted to increase the amount of capital per worker. That there has been a significant overinvestment is a definite possibility. If so, the marginal productivity of investment is very small or even negative. The chief problem may be that the workforce is not capable of assimilating higher levels of technology introduced at such a fast rate.

For Poland, one finds that whichever set of statistics on growth of investment or capital stock is chosen, the high growth rate of the economy since 1971 can be attributed mainly to an investment boom, associated with large increases in nonagricultural employment. Fallenbuchl shows that the average rates of growth of both accumulation and fixed capital investment in 1971–75 were the highest since 1950 (his Table II) and that, despite the serious neglect of infrastructure in the past, the proportion of total investment allocated to

<sup>18</sup> For Poland, this is not obvious from the aggregate statistics which do not show the increased participation rates in agriculture.

<sup>19</sup> The discussion below by country focuses only on selected issues of capital and labor inputs and the measurements of productivity; credits and changes in terms of trade are discussed in Sections B and C, respectively.

so-called non-productive investments declined during this recent period. Fallenbuchl sums up the Polish experience with regard to factor inputs:

In its overall rate of investment and in the structure of investment allocations among the major sectors of the economy, this was just another orthodox Stalinist investment drive, undertaken within the basically orthodox system of central planning and management.<sup>20</sup>

He offers a most interesting insight as to how the investment boom got out of control:

The excessively high rate of investment happened not because of an increased degree of autonomy of economic organizations [the reason Portes gives for the large fluctuations of investment in Hungary], but because there was a general expansionary attitude at all levels of the administrative structure \* \* \*. There also seemed to appear a tendency for \* \* \* a "multi-center direction of the economy," with the Central Planning Commission, the Central Committee and the Presidium of the Council of Ministers each making its own decision in response to different pressures from local party and state authorities, the industrial branch ministries, and lobbying by various managers of economic organizations. [Everyone attempted] to "hook on to the plan," \* \* \* on the basis of unrealistically low estimates [of investment costs], knowing well that once the project is included in the plan, it will subsequently receive all that is needed for its completion.<sup>21</sup>

And as to how this investment boom was financed, Fallenbuchl points out that while earlier excessive investment drives collapsed within two or three years, this drive could last longer because foreign capital was imported on credit, and on a very large scale.

For Hungary, Portes calls attention to the difficulty of getting a good handle on the relative importance of capital formation in total resource use. He points out that the share of capital formation appears substantially higher in the GNP accounts (Table 3) than in the NMP accounts (Table 2). He concludes that since capital stock in industry grew at 8 percent and industrial labor force only 1 percent per annum, any reasonable weighting system would give a fairly health growth rate of total factor productivity in industry. He also notes the fairly wide fluctuations over time in investment around a rising trend, which he attributes to the large role played by enterprises in initiating, but not necessarily financing investment projects.

For Czechoslovakia, Holesovsky stresses how difficult it is to estimate the share of GNP or NMP devoted to investment. He presents a wide range of alternative estimates and points out that the data provided by the statistics of some East European countries understate the investment shares because their market prices understate the value of producer goods as compared with more realistic valuation based on factor costs. He also stresses the low marginal efficiency of capital in Czechoslovakia, "due to a combination of a slow infusion of technical progress embodied in new producer goods, and systemic disabilities concerning effective utilization of new productive assets; independently of their quality" (p. 705).

For the GDR, Keren stresses that the increased output was achieved without any growth in labor input. Based on the increase in capital stock—estimated by Keren to have been 5 percent per annum during 1965—and 6 percent during 1970–75—the author estimates the rise in factor productivity under various assumptions (Table 8).

### B. Foreign Borrowing and Lending

A country able to borrow needed resources from abroad has access to a source of growth to supplement its domestic efforts. If a country lends abroad, this reduces the resources available to finance domestic consumption or investment; hence, it represents a negative source of growth.

All East European countries except Albania have recently become net borrowers from the West.<sup>22</sup> Since 1961, Albania has been a large borrower—or grantee—from the People's Republic of China. The six East European members of the CMEA are net lenders to the East, principally to the USSR, through their participation in so-called CMEA joint investment projects. (Periodically, the USSR also makes large loans to individual East European countries.) They also run trade surpluses with the less developed socialist countries, principally Mongolia and Cuba, participating in what might be called intra-socialist foreign aid programs. The East European countries occasionally also invest in projects located on the territory of an East European partner; but intra-East European credit flows are small and hence can be disregarded. Finally, several East European countries extend credits to finance the sale of their machinery exports to less developed countries.

#### HARD-CURRENCY BORROWING FROM THE WEST AND THE SPECIAL CASE OF ALBANIAN CREDITS FROM CHINA

An excellent contribution in this volume summarizes the known facts about the six East European countries' net indebtedness to the West.<sup>23</sup> Each country study adds important details on the reasons for and pattern of borrowing and the repayment burden that has been created. Our purpose here is to establish the relative importance of borrowed resources as a factor contributing to the growth performance of these countries and to include in the comparative assessment Yugoslavia's indebtedness to the industrial West and Albania's net borrowing position vis-a-vis all countries since 1961, principally the PRC. Although Albania's borrowing has not been predominantly in hard currency, its inclusion in the comparison is appropriate because the resources it obtained came from outside the region. The fact that much of the credit it has received may have been (or will be) forgiven, whereas the rest of East Europe will repay what it has borrowed, is an important distinction when considering the burden of indebtedness but not its contribution to growth, in the short run.<sup>24</sup>

<sup>22</sup> For a comprehensive survey of the Western perspective on lending money to centrally planned economies, see Paul Marer (ed.), "U.S. Financing of East-West Trade: The Political Economy of Government Credits and the National Interest" (Bloomington, IN: International Development Institute and Indiana University Press, 1975).

<sup>23</sup> J. C. Zoeter, "Eastern Europe: The Growing Hard Currency Debt." Net indebtedness is gross indebtedness less deposits in banks located in the West.

<sup>24</sup> In judging how much additional resources an increase in indebtedness provides, interest charges paid on the debt should be subtracted. If Albania pays no interest or obtains a subsidized rate, then the contribution of borrowed resources will be greater to its economy than those East Europe obtains from the West. However, the fact that all of Albania's borrowings have been tied to specific goods offered by the lender, whereas only some of East Europe's borrowings have been tied, is an offsetting consideration. (In the case of East Europe, credit, when tied, is not to specific goods but to any supplier in the lender's country, which is a less severe constraint than that faced by Albania.)

To compare the relative importance of borrowed resources for the East European economies, Table 4 juxtaposes the increase in indebtedness with the increment of the same country's GNP during the same period, both expressed in current U.S. dollars. 1967 was chosen as the base year because before then borrowing from the West was not on a significant scale. 1972 and 1975 were selected as years dividing the subperiods because the indebtedness position of some countries changed considerably and current dollar GNP estimates were available.

<sup>1</sup> From Dec. 31, 1967 until Dec. 31, 1972.<sup>2</sup> Weighted average.<sup>3</sup> Social product.<sup>4</sup> Not available.<sup>5</sup> 1967-75.<sup>6</sup> Cumulative import surplus, principally with the People's Republic of China.

Source: GNP in current dollars for the East Europe 6, 1967: T. P. Alton, "Defense Expenditures in Eastern Europe, 1965-1976," table I. Yugoslavia: "World Tables, 1976," (Baltimore: Johns Hopkins University Press), pp. 388-9; Albania: 1970 GNP in current dollars is calculated by Kaser and Schnytzer in their contribution in this volume, pt. I, p. 574 as \$748,000,000, I arbitrarily assumed that

1967 GNP in current dollars was 40 percent lower, 1972 GNP 25 percent higher, and 1975 GNP 40 percent higher than 1972.

Year-end hard-currency indebtedness of the East Europe 6 in 1967 is shown in E. Snell, "Eastern Europe's Trade and Payments With the Industrial West," in "Reorientation," tables 1-6; in 1972, 1975; and 1976 in J. C. Zoeter, "Eastern Europe: The Growing Hard-Currency Debt," tables 1 and 2; Yugoslavia: figures of \$1,900,000,000 at the end of 1970 and 5,600,000,000 at the end of 1975 are cited in Tyson; other years interpolated on the basis of information provided by experts at leading U.S. commercial banks. Albania: cumulative import surplus in 1966-70 of \$246,000,000 and in 1971-75 of \$492,000,000 is shown in M. Kaser's contribution (pt. III, p. 1327). In each period I assumed that the annual deficit grew by gradually rising amounts.

Ranking countries by the highest to the lowest ratio of increase in indebtedness to incremental GNP during 1967-76, we find that Albania is in a class by itself. The resources it was able to obtain abroad were of the same order of magnitude as the increments to its GNP. Albania's unique position in Eastern Europe is further strengthened if we consider that since World War II it has relied continuously on large infusions of foreign resources (whereas East Europe was not borrowing on a significant scale before the mid-1960s) and that a substantial portion of those resources were obtained, or became, grants rather than loans.

Focusing on the entire 1967-76 period, the remaining seven countries fall into two groups. The increase in debt was 10 percent or more of the increase in GNP in Yugoslavia (17 percent), Poland (16 percent), Hungary (15 percent), Bulgaria (13 percent) and the GDR (11 percent); and less than 10 percent in Romania (8 percent) and Czechoslovakia (5 percent). But if we focus on subperiods, the ratio of incremental debt to incremental GNP was much greater for particular countries than for the period as a whole. In 1976, for example, the ratio was almost one third in Bulgaria and more than one-third in Hungary and Poland, matching the similar high figures for Yugoslavia in the earlier periods.

The incremental debt/GNP ratios are influenced greatly by differences in economic performance among countries, depressing the ratios of fast-growing countries, such as Romania, and uplifting the ratios of relatively poor performers, such as the GDR. A more straightforward indicator of the relative importance of borrowed resources is the relationship between total indebtedness and total GNP (affected also by performance) and total indebtedness to total population (both shown in Table 5).

TABLE 5.—RATIO OF TOTAL INDEBTEDNESS TO TOTAL GNP AND TOTAL POPULATION, 1967, 1972, AND 1976  
[Percent and current dollars]

Country	Ratio of total indebtedness to GNP (percent)			Per capita indebtedness		
	1967	1972	1976	1967	1972	1976

<sup>1</sup> Weighted average.

<sup>2</sup> 1975.

Sources: GNP and debt: see table 4; population: see table 3.

By 1976, the total indebtedness equalled or exceeded 10 percent of GNP in all countries except the GDR (7 percent), Romania (6 percent), and Czechoslovakia (4 percent). On a per capita basis, the countries rank from most to least resources borrowed, as follows:

Albania.....	365
Yugoslavia.....	300
Poland.....	297
GDR.....	286
Bulgaria.....	263
Hungary.....	255
Romania.....	149
Czechoslovakia.....	141

#### CREDITS TO AND FROM THE USSR

Not enough information is available on East European trade with the USSR to establish the magnitude of the net flow of resources between the countries. Although trade balances can be determined on the basis of published Soviet or East European trade figures, lack of information on whether trade in military items is included, and differences among the CMEA countries in recording trade flows, make conclusions about the actual trade balance difficult to reach.<sup>25</sup> Moreover, even if the trade balance could be determined accurately, it would be difficult to estimate net resource transfers without a painstaking investigation of (1) the amount of investments East European countries have pledged to carry out in the USSR, and the USSR in Eastern Europe, and the scheduling of deliveries connected with these investments; (2) transactions connected with contributions to and receipt of credits from the CMEA Investment Bank; (3) the mechanism of settling with commodity deliveries net balances of invisible transactions and military items; and (4) switch trade, under which credit or debit balances with a CMEA partner are offset with debit or credit balances extant with third countries outside the CMEA area.

One of the most important (if not the most important) item determining resource transfers between the USSR and the six East European countries is East European participation in CMEA investment projects, the largest ones located in the USSR. East European investment in Soviet resource development is not new. But whereas during the late 1950's and 1960's these credits were typically small, bilateral and designed mainly to increase the capacity of existing projects, since the signing of the Comprehensive Program in 1971, there has been a dramatic increase in the size and number of these projects, and with multilateral participation (but not ownership). The largest and by far the most important project is the \$5 billion (initial cost estimate) Orenburg natural gas pipeline channeling gas from Soviet fields to Eastern Europe, scheduled to be completed in 1978. Each East European country except Romania agreed to build a section of the pipeline (Romania is providing only pipe and equipment), supplying labor and above-plan deliveries of equipment, technical services and the hard-currency with which to import the pipes and other machinery that must be purchased in the West.

The valuation of the individual countries' contribution to the project and the financing arrangements were not published. But it is known that early in 1976 the International Investment Bank (IIB) of the CMEA borrowed \$600 million on the Eurodollar market for the Orenburg project and provided these funds to the USSR which has

<sup>25</sup> Concepts of Soviet and East European trade reporting and analytical problems arising thereof are discussed in Paul Marer, "Soviet and East European Foreign Trade, 1946-1969: Statistical Compendium and Guide" (Bloomington, IN: Indiana University Press, 1972), Appendices A through F.

made purchases, largely of pipe, for the entire project. The East Europeans owe the IIB for their share of the Soviet hard-currency purchases and, according to IIB rules, must repay in hard currency at world market rates of interest. However, this credit covers less than half of the cost of the 2 million tons of large-diameter pipes (estimated cost \$1.5 billion), and there is equipment (such as compressor stations) that are also being purchased from the West. So either the IIB will take up other major credit or the East European countries themselves will have to provide hard currency for the centralized purchase of pipes and equipment.<sup>26</sup>

As Haberstrah reports in his contribution in this volume, the Soviets are probably disappointed with the East European contribution to this project up to now. Due to shortages of both hard currency and technical services plus labor skilled in pipeline construction, each country has already reduced its commitment and, except in the case of Poland, much of the actual pipeline construction will be done by the Soviets themselves. Hungarian economists, however, stress that not a reduction but a transformation in the individual country's commitment has been taking place lately. Hungary and some other East European countries are finding that rising national currency costs and lack of specialization in certain tasks, such as the laying of pipelines, which each country was supposed to perform in the USSR, makes it more attractive (1) to commission other countries to perform some of the installation (in the case of Hungary, Poland will help out)—since the initial contract provides that the signatory countries can redistribute the scope of the tasks among themselves; and (2) to increase the share of the country's hard-currency contribution to the USSR in fulfillment of its obligation to the project.<sup>27</sup>

The reader is referred to Snell's interesting calculations (in this volume) of East Europe's projected 1976-80 balance of payments with the USSR. He shows that the East European countries, excluding Hungary, plan to run an approximately \$9 billion trade surplus, at 1975 CMEA trade prices, with the USSR. This is explained by participation in joint projects in the USSR, deterioration in their terms of trade, and (more speculatively) payment for military hardware. The largest surpluses are projected for Poland and the GDR (\$3.3 billion each), followed by Romania (\$1.3 billion), Bulgaria (\$0.9 billion), and Czechoslovakia (\$0.3 billion).<sup>28</sup> Hungary is the only European CMEA country that expects to run a large, cca \$2 billion trade deficit with the USSR. This almost certainly reflects the yet unpublicized large credits the Soviet Union granted to Hungary, payable in the 1980s, to help smooth that country's adjustment to the energy crisis.

<sup>26</sup> J. Bethkenhagen, "Joint Energy Projects and Their Influence on Future COMECON Energy Autarchy Ambitions," paper presented at the NATO Colloquium on COMECON Integration, Brussels, March 16-18, 1977.

<sup>27</sup> Personal interview with Hungarian and Polish economists, April, 1977. One may wonder which of the following forms does the so-called hard-currency contributions take: (1) cash; (2) transshipment of goods purchased in Western countries; or (3) so-called "dollar-price-settlement" exports, i.e., goods produced in Hungary and sold "above plan" on the CMEA market at current world prices (see discussion below). Our guess is that it takes mainly this last form.

<sup>28</sup> Snell, "East European Economies," Table 10, related discussion in the text, and Appendix F. The low figure for Czechoslovakia may be partly explained by the country building on its own territory a gas pipeline to transport Soviet gas to Western Europe, a contribution to the Soviet Union which will not show up in trade statistics. Moreover, in 1966 Czechoslovakia supplied to the USSR on credit \$550 million in pipes and machinery in return for 60 million tons of oil to be shipped during 1971-80.

An adjustment downward of East European credits to the USSR from planned 1976-80 levels may be agreed to by the USSR. This already occurred in November 1976 when a low-interest, \$1.3 billion loan by the Soviets to Poland was reportedly agreed upon, comprised of above-plan deliveries during 1977-80 of raw materials, food, and machinery.<sup>29</sup>

In commerce between two countries, aid can be given (or a grant extracted) by trading at prices which deviate, on balance, from opportunity costs on the world market. Arising from the special pricing system in effect on the CMEA market, under which historical rather than current world market prices are used, during 1971-74 the Soviet Union's terms of trade with Eastern Europe gradually deteriorated by an estimated 30 to 40 percent below the levels which would have prevailed if Soviet-East European prices had moved in conformity with changes in world prices.<sup>30</sup> Almost all of this "grant" was accounted for by not following immediately the dramatic rise of oil prices on the world market. This benefited the five oil importing countries, Romania not among them. The 1975 doubling of oil prices to Eastern Europe still permitted the five to buy energy cheaper from the Soviet Union than from the world market.<sup>31</sup>

To conclude: in terms of trade flows for Eastern Europe, commerce with the Soviet Union is of the same order of magnitude as commerce with the industrial West (much larger for Bulgaria and much smaller for Romania). But while the direction and approximate order of magnitude of net resource transfers from the industrial West to Eastern Europe can be unambiguously ascertained, the situation in East Europe-Soviet relations is much more complicated, and quantification is much more difficult. On balance, however, during 1970-76 the East European countries appear to have benefited from a net resource transfer from the USSR, if their trade relationship is viewed in a static rather than dynamic setting. (That is, static gains from trade that arise from net resource transfer would have to be juxtaposed with dynamic losses that arise from the benefits forgone if a preferential or "sheltered" Soviet, and CMEA, market absorbs over a long period poor-quality goods and obsolete equipment, thereby reducing the incentive to innovate and produce for the market.) But during 1976-80, the resource transfer will almost certainly be in the other direction, the main reasons being a deterioration in the terms of trade (see below) and investing in the joint projects.

#### CREDITS TO LESS DEVELOPED COUNTRIES

It is believed that all East European countries except Albania regularly extend sizable credits to less developed countries (LDCs) to finance machinery exports. For some East European countries, these credits are reflected in the trade surplus that is reported or can

<sup>29</sup> David Lascelles, "Soviet Aid Package for Poland Includes \$1.3 Billion Loan," *Financial Times*, November 20, 1976, as cited in G. R. Teske, "Poland's Trade with the Developed West: Performance and Prospects," in this volume, Section IV-B. The USSR also allowed the GDR to run up a sizable, presumably unplanned, deficit in 1975 (Keren, p. 722).

<sup>30</sup> Martin Kohn, "Developments in Soviet-Eastern European Terms of Trade, 1971-75," in "Soviet Economy in a New Perspective" (Washington, D.C., Joint Economic Committee of the U.S., 1976), pp 75-76.

<sup>31</sup> The broad economic and political context in which Soviet decisions are made on the prices and quantities of goods traded with Eastern Europe are discussed in Paul Marer, "Has Eastern Europe Become a Liability to the Soviet Union—The Economic Aspects," in Charles Gati (ed.), "The International Politics of Eastern Europe" (New York: Praeger, 1976).

be calculated. But even East European countries that show a deficit with LDCs give sizable, low-interest credits. Deficits may arise as earlier credits are repaid by the LDC debtors or because LDCs supply raw materials and energy to East Europe, often for hard currency.

Bulgaria is shown to be running a trade surplus with LDCs, about 600 million devisa-leva (SDR 513m) cumulatively during 1970-75 (Allen, Table 13). Czechoslovakia has been one of the large creditors and machinery suppliers to LDCs since the 1950s; during 1970-75 achieving a 5 billion devisa-crown (SDR 694m) surplus with the Third World (Holesovsky, Table 3). The GDR had a surplus until 1973, which turned into a sizable deficit during 1974-75, possibly explained by new Middle Eastern sources or higher prices for energy (Keren, Table 13). Hungary had a small deficit with LDCs during much of the 1970s (Portes, Table 26), while Poland ran a deficit of 2.1 billion devisa zloty (SDR 525m) during 1970-75 (Fallenbuchl, Table XIII).

Romania presents a very interesting case. Montias shows that Romania ran large surpluses throughout the 1960's and early 1970's. He argues that—

Because exports of manufactures to LDCs must be lubricated with credits and because repayment is generally tied to bilateral accounts, the possibilities open to Romania of solving her trade and payments problems via exchanges with LDCs would seem to be limited (Montias, p. 874).

Jackson, in his contribution on Romania, calls attention to a new Romanian strategy to import directly from LDCs commodities which have been purchased through Western intermediaries and to pay with manufactures exports, technical assistance, and construction services (pp. 889-890). Thus, while Romania may not be able to generate substantial hard currency via an export surplus with LDCs, which is Montias' point, it may be able to save hard currency by redirecting purchases from Western intermediaries to LDC producers, which is Jackson's point. Romania apparently has had success with that policy: the share of LDCs in Romania's total trade increased from 9 percent in 1973 to 19.5 percent in 1975, with extraordinary further increases to 25 percent by 1977-78 and a projected 30 percent (!) by 1980 (Jackson, p. 912).<sup>32</sup>

Yugoslavia pursues a policy vis-a-vis LDCs quite similar to the rest of Eastern Europe. Even though its trade with LDCs has been in deficit, most likely because of the oil it imports from Middle East countries, it has been pursuing "preferential credit policies and long-term cooperation agreements to promote exports and preferential tariffs to promote imports" (Tyson, p. 986).

In conclusion, although it is difficult to determine the magnitude of credits (usually at very low interest rates) the individual East European countries have extended to promote exports to LDCs, the policy appears to have been practiced widely and will probably gain further momentum for economic as well as political reasons.

### *C. Terms of Trade*

Implicit in our discussion on foreign borrowing and lending was the assumption that (a) an increase in East Europe's indebtedness provides additional resources for growth, and (b) credits granted

<sup>32</sup> It is possible that some of this increase reflects mere bookkeeping, such as moving from a "country of purchase and sale" reporting system to a "country of origin-destination" system. This is implied by the Ceausescu quote cited by Jackson in his footnote 27.

by East Europe reduce the amount of resources that can be harnessed for development, at least in the short run. This assumption needs to be modified; only by considering changes in a country's terms of trade can we determine, for example, whether foreign borrowing has provided additional resources or whether it was needed simply to cover the higher price of imports which remain uncompensated by the higher price of exports.

#### TOTAL TRADE

Export and import price indices and terms of trade for 1970-75 have been published or can be derived for five East European countries (see Table 6).

TABLE 6.—EXPORT AND IMPORT PRICE INDICES AND TERMS OF TRADE OF 5 EAST EUROPEAN COUNTRIES, 1970-75  
[1970 equals 100]

Sources: Bulgaria: M. Allen's contribution, table 11, converted from 1960 to 1970 base; GDR: M. Kerén's contribution, table 12; Hungary: "Külkereskedelmi Statisztikai Évkönyv" (Budapest: Central Statistical Office, 1976), p. 411; Poland: Z. Fallenbuchl, et al., "East European Reactions to International Commodity Inflation," essay in this volume, table 1, converted from annual percentage change to 1970 base; Yugoslavia: op. cit., table XXII, converted from annual percentage change to 1970 base.

The terms of trade did not change significantly until 1973, but then deteriorated by 17 percent for Hungary, 14 percent for the GDR, 5 percent for Yugoslavia, 4 percent for Bulgaria, and improved by 3 percent for Poland. Czechoslovakia's terms of trade were probably similar to those of the GDR, while Romania's were probably closer to Poland's. No price data are available on Albania's trade, so Kaser (in contribution to this volume) applied Yugoslav export and import price indices to estimate the quantum of Albania's trade between 1948 and 1970 (Table V-1). One may speculate that since Albania is self-sufficient in energy and a large share of its exports is comprised of raw materials, since 1970 its terms of trade have probably improved. Schnytzer supports this speculation:

The world prices of manufactured goods did not rise as rapidly in 1974 as the prices of Albania's major exports: oil, chromium, copper and agricultural produce. Thus, on the basis of the Oil Crisis, Albanian industry should have benefited if not remain unaffected (p. 633).

But since Albania trades predominantly with China and the pricing mechanism they use is not known, any conjecture about Albania's terms of trade is highly speculative.

#### SOCIALIST AND NONSOCIALIST COUNTRIES

Price trends and terms of trade are known to differ in trade with socialist and nonsocialist countries not only because the commodity compositions differ in the two directions but also because prices in intra-socialist trade follow world market price changes with several years' lag.

Separate price and terms of trade indices with these two groups of countries are available only for Hungary and Poland, and these are shown in Table 7.<sup>33</sup>

TABLE 7.—EXPORT AND IMPORT PRICE INDICES OF HUNGARY AND POLAND WITH SOCIALIST AND NONSOCIALIST GROUPS OF COUNTRIES, 1970-75

<sup>1</sup> Soc.—Socialist countries; R.S.—Ruble-settlement countries; N.S.—Nonsocialist countries; D+O—Dollar and other devisa-settlement countries.

<sup>2</sup> Advanced industrial countries for Poland only.

Sources: Hungary: see table 6 (socialist/nonsocialist shown on pp. 414-15 converted from 1960 to 1970 base); Poland: see table 6.

<sup>33</sup> Price indices for earlier periods are shown in Paul Marer, "Postwar Pricing and Price Patterns in Socialist Foreign Trade (1946-1971)" (Bloomington, IN: IDRC Report 1, 1972).

Two slightly different price and terms of trade indices are shown for Hungary under each of the two main headings: one calculated on the basis of country of export and import (called socialist vs. nonsocialist trade), the other on the basis of the settlement price (currency?) used (called ruble vs. dollar settlement trade). The difference is that a certain portion of trade with CMEA partners—usually comprised of above-plan “hard good” exports and imports—is priced according to current world market prices. This commerce is included under “socialist” but excluded from “ruble-settlement” trade.<sup>34</sup> The suggested estimation procedure is outlined in the Appendix and illustrated with data for 1975.

Table 7 reveals that between 1972 and 1975, in trade with socialist countries Hungary's export prices rose by 17 to 19 percent while its import prices increased by 32 to 39 percent, resulting in a deterioration in its terms of trade by 12 to 15 percent (depending on whether or not dollar-priced trade is excluded). Since the commodity composition of GDR and Czechoslovak trade with the socialist countries is not too different from that of Hungary, one may reasonably speculate that their terms of trade would also be comparable. Poland, on the other hand, is in a much better situation: since it is both an exporter and importer of energy and raw materials, its terms of trade with all socialist countries as a group did not change much. The terms of trade of Romania, which neither imports nor exports energy in trade with its socialist partners, probably did not change very much either. Bulgaria's terms of trade vis-a-vis socialist countries probably falls between that of Hungary and Poland.<sup>35</sup>

In trade with nonsocialist countries, during 1972-75, Hungary's terms of trade deteriorated by about 20 percent while Poland's improved (with the industrial West only) by more than 20 percent, thanks to coal which made up 30 percent of Poland's hard-currency exports in 1975.<sup>36</sup> The terms of trade of the other East European countries would be influenced greatly by the commodity composition of their exports to the West: the larger the proportion comprised of fuels (SITC 3) and other primary products (SITC 0+1+2+4), the more they were helped, or the less hurt, by developments during 1972-75 on the world market. Based on data compiled by Wolf, the 1975 compositions of East European countries' exports to the twelve main West European countries were as follows:<sup>37</sup>

	Fuels (percent)	Primary products	Manufactures	1975 terms of trade (1970=100)
Poland.....	37.0	25.0	38.0	122.5
Romania.....	20.8	28.3	50.8	(100.0)
Czechoslovakia.....	14.3	20.3	65.4	(90.0)
German Democratic Republic.....	6.8	23.2	70.0	(80.0)
Hungary.....	2.1	43.1	54.8	(80.0)
Bulgaria.....	1.9	48.2	49.9	(80.0)

<sup>1</sup> Average of “nonsocialist” and “dollar-price settlement” trade.

<sup>34</sup> There is some question whether socialist “dollar” trade is only priced at current world prices or is also settled through hard-currency payments.

<sup>35</sup> This speculation is consistent with Bulgaria's terms of trade indices in its total trade (see Table 6).

<sup>36</sup> See contribution in this volume by Teske, Appendix A.

<sup>37</sup> Thomas A. Wolf, “East-West European Trade Relations,” in this volume, Table 3. The structure of imports also affects the terms of trade, but the composition of East European imports is more similar than exports.

Shown in parentheses in the last column are my rough estimates of the terms of trade of the five East European countries for which data are not available. The estimates are based on the commodity composition of these countries' exports to Western Europe and the terms of trade indices of Poland and Hungary.

With respect to nonsocialist trade, the tentative conclusion is that Poland was the only East European country that obtained resources from the West; not only through borrowing large amounts but through an improvement in its terms of trade. Romania was probably neither hurt nor benefited much in its Western trade from price developments on the world market, but the other four countries had to devote a significant part of the resources borrowed from the West to maintain the real volume of their imports in the face of deteriorating price relations. Moreover, it seems that the same countries that were most hurt by price developments in their trade with the West were also adversely affected in their trade with socialist countries, although the brunt of the impact has been delayed by a few years. Most important, of course, is the terms of trade with the USSR, to which we turn next.

#### TRADE WITH THE USSR

During 1970-74, Soviet-East European terms of trade did not change significantly.<sup>38</sup> Soviet crude oil to Eastern Europe in 1974, for example, was under \$20/ton, or about one-quarter of the world price. In January 1975, one year before the expiration of the fixed CMEA price agreement, the Soviet Union nearly doubled oil prices to CMEA, providing substantial additional income to the USSR: 1.4 billion transferable rubles (almost \$2 billion) equal to total Soviet imports from Hungary in 1975. In that year, energy accounted for 25 percent of Soviet export proceeds from Eastern Europe.

Based on detailed but not fully specified quantity and value data published by the USSR, two experts independently calculated changes in Soviet-East European terms of trade from 1974 to 1975 (see Table 8).

TABLE 8.—SOVIET EXPORT AND IMPORT PRICE INDICES AND TERMS OF TRADE WITH 6 EAST EUROPEAN COUNTRIES, 1975

[1974=100]

Sources: 1974 weights and 1975 column A: M. J. Kohn and N. R. Lang, "The Intra-CMEA" table 1; column B: Raimund Dietz, "Terms of Trade im sowjetischen Aussenhandel gegenüber den RGW-Ländern in Osteuropa" (tentative title) (Vienna Austria: Wiener Institut für Internationale Wirtschaftsvergleiche, 1977, forthcoming).

<sup>38</sup> Martin Kohn, "Developments."

Depending upon the choice of weights and the small differences in methodologies used, in 1975 East Europe's terms of trade deteriorated vis-a-vis the USSR by 11 to 14 percent,<sup>39</sup> with the largest loss suffered by the GDR, Czechoslovakia, and Hungary, somewhat smaller for Bulgaria, and only 3 to 4 percent for Poland and Romania. Thus, Soviet terms of trade calculated from Soviet data are fully consistent with the indices computed for Hungary and Poland and the speculative estimates made for trade terms with socialist countries on the basis of findings for these two countries.

Kohn and Lang calculated that the negative impact of deteriorating terms of trade with USSR in 1975 in effect forced the four most seriously affected countries to give up resources by amounts equivalent to roughly 1 percent of GNP for the GDR, Hungary and Bulgaria, and over 0.5 percent of GNP for Czechoslovakia (p. 142).

Further increases in oil prices during 1976 were moderate: but in 1977, 1978, and 1979 substantial further increases can be expected. This is because of the new system of setting intra-CMEA prices on the basis of moving-average world market prices. According to the new price rules reportedly agreed upon, 1975 prices were based on a three-year (1972-74) world average, changed to a five-year world average in 1976 (1971-75). Thus, 1977 prices will be based on 1972-76 world prices, 1978 prices on 1973-77 world prices, and so on. Applying this price-setting system to past and prospective future world prices of oil, in 1977 and 1978 the East European countries will have to pay about 25 percent each year and in 1979 about 20 percent more than during each previous year. By 1980, the price level may be stabilized.<sup>40</sup>

#### *D. In Lieu of Conclusions*

Probably no other country in East Europe is more adversely affected by a combination of worsening price developments, the investment participation required in the USSR, and the hard-currency debt service burden than the GDR. Therefore, Keren's reasoning and quantification of what these developments signal for East Germany in terms of growth prospects is of particular interest, for the methodology which is applicable to the other East European countries as well as the specific figures he derives:

In 1970 \* \* \* the share of exports and imports was about 31 percent each of NMP. [But by 1975, the deterioration in the terms of trade meant] that to balance imports quantity-wise, exports would have to rise by another 15 percent \* \* \* nearly 5 percent of NMP, nearly 4 percent of GNP.

Without any other changes in the price level on Western markets, we know that prices on CMEA markets are going to adjust to the present Western prices by the end of the decade. Assuming that the total deterioration in the terms of trade will amount to 20 percent, the damage by 1980 will be [a further more than] 6 percent of NMP if the ratio of imports in NMP does not change. [But if] foreign trade continues to increase at a rate 60 percent faster than NMP, and NMP rises by 26 percent [as planned] by 1980, imports should rise by over 40 percent to some 35 percent of NMP, and the damage in terms of growth of exports will amount to 7 percent of the 1980 NMP.

[But] balancing accounts in 1980 is not sufficient. Assuming that (1) the GDR leadership wants debts [to the West] to remain at their present [1975] level in 1980, and that only additional deficits amassed during the first two years of the present

<sup>39</sup> Actually, the percent deterioration for East Europe is slightly less than the percentage improvement for the USSR. If Soviet export price indices are assumed to be East European import price indices, etc., then the deterioration in East Europe's terms of trade would be 10%, 13%, and 10% in the 1974 weights and 1975 A and B columns, respectively.

<sup>40</sup> J. Bethkenhagen, "Joint Energy \* \* \*."

FYP are to be repaid during the final two years; and (2) participation [by the GDR in projects in the USSR] of 8 billion Marks over the 1976-80 FYP at annual rates and \* \* \* sum up all the increases [required] in exports: 7 percent to balance trade at the [worsened] terms of trade, 2 percent to keep the deficit at the present level, and 1 percent for investment in CMEA, altogether 10 percent of 1980 NMP will be used up by increased exports. Any smaller room for increasing the export surplus means an increase in indebtedness; any larger share, a reduction of indebtedness [pp. 744-746].

## V. ECONOMIC STRATEGIES, SYSTEMS, AND POLICIES

To provide an overview for the eight East European countries on these issues, the task is more manageable and the comparisons more meaningful if the countries are divided into two groups: the Southern Tier, comprised of the Balkan countries of Bulgaria, Romania, Yugoslavia, and Albania, which on the basis of official statistics, have been growing more rapidly than the rest of Eastern Europe (except Poland), and the Northern Tier, comprised of the more highly developed but still very diverse nations located to the north of the Balkans, the GDR, Czechoslovakia, Hungary, and Poland.

Findings for the four Balkan countries are discussed comparatively and in some detail. But only a shorter summary, highlighting particular issues, is made for the Northern Tier countries because: (1) the basic facts about the economic systems, strategies, and policies of these countries are better known than those of the Balkan countries; (2) partly for this reason, the contributions on these countries tend to be shorter, so there is less need to provide a guide to the issues; and (3) the four northern countries are analyzed in numerous studies included in the other sections of this volume, while at least two of the Balkan countries, Yugoslavia and Albania, tend not to be discussed in these studies.

### A. Southern Tier (Balkan) Countries

#### BROAD ECONOMIC STRATEGY

Bulgaria, Romania, Yugoslavia, and Albania share the Balkan historical region (along with Greece), and have in common the fact of economic backwardness and foreign domination before World War II. Although the economic system and political orientation of Yugoslavia are quite different from the rest of Eastern Europe, "it seems useful to examine Yugoslavia within the East European context because the Yugoslav system has grown out of East European roots, and consequently, represents a possible path for further socialist transformation within the [region]" (Tyson, p. 941).

Yugoslavia and Albania are very similar in one respect: both had continuous leadership since the war. Tito in Yugoslavia and Hoxha in Albania came to power as leaders of a liberating army and initially without Soviet backing.

Three of the four countries have quarrelled with Moscow; the fourth country, Bulgaria, has been consistently one of its staunchest allies. The common denominator of the economic systems, strategies, and policies of the first three countries has been a quest for and preservation of independence. In the case of Yugoslavia, this is so well known that it would be superfluous to document it. In the case of Romania, the political aspects are well known, but spelling out its economic

policy implications is one of the important contributions of Jackson's essay. And in the case of Albania, Kaser and Schnytzer make the case that pursuit of independence has been the catalyst which explains Albania's domestic and foreign economic policy since World War II.

Perhaps the single key to Romanian policy since the 1950s, argues Jackson, has been the pursuit of independence under constraints. Since the leadership believes that a backward, unindustrialized country has no hope for independence, the first priority has been and remains rapid industrialization. The Romanians recognize, however, that industrialization breeds new threats to independence if countries supplying raw materials, capital, and technology and providing markets impose conditions which may hinder further development. The Romanians chose to reduce this threat by (1) limiting the level of imports via import substitution; (2) distributing imports among many domestic branches to avoid excessive specialization; and (3) diversifying imports and exports as much as possible among countries. This last strategy explains in part, Jackson argues, Romania's increased orientation toward the LDCs: nearly one-third of Romania's commerce is scheduled to be with Third World countries by 1980.

In its drive to achieve economic independence, Romania had a significant edge over its Balkan (as well as other East European) neighbors: energy independence. In 1974, it could supply 86 percent of its needs from domestic sources, claimed to be the highest rate of energy self sufficiency in Europe.

Romania received no significant aid from East or West (unless one classifies large commercial credits as aid). In contrast, Bulgaria has received favorable economic treatment from the Soviet Union, as was documented earlier; Yugoslavia had been a recipient of Western aid as well as substantial remittances from its nationals working in Western Europe; while Albania had obtained large aid from the CMEA countries up to 1961 and from China since then. So, on this comparison, Romania has been the most self-reliant.

Can one reconcile Albania's apparently close political alliance and economic aid relationship with the USSR until the late 1950's and with China since the early 1960's with a policy of independence? Yes, argue Kaser and Schnytzer. The main threads of their arguments on this theme are:

1. Strict central planning a la Stalinist Soviet model had been accepted by the present leadership before it came to power in 1945 as inherently the correct path for Albania, although comprehensive central planning could be introduced only gradually because there was little industry to plan during the first ten years of Communist rule (Part II, p. 584).

2. This ideologically-rooted belief explains why neither the death of Stalin in 1953 nor his denunciation by Khrushchev in 1956 had any immediate effect on Albanian economic organization or planning (Part II, p. 586).

3. For these reasons, and because Soviet rapprochement with Yugoslavia in the late 1950's appeared to pose a threat to Albanian independence, the turn to China as a protector of the country's independence was made. And because of the distance, Albania's desire for independence in domestic policy determination would

be more likely to be assured by China than the USSR (Part IV, p. 623).

4. That Albania does not follow all Chinese policies which have domestic economic and political implications is illustrated by Albania ignoring China's opening its doors to the West. Although there apparently was a debate on this and related issues during 1972-75, the victorious (Hoxha) faction felt so strongly about maintaining economic independence from the West that the new constitution adopted in 1975(?) prohibits "granting concessions to . . . as well as obtaining credits from . . . bourgeois and revisionist capitalist monopolies and states." See "Trade and Aid in the Albanian Economy," part III of this volume, pp. 1325-1340.

5. Albania is the poorest country in Europe. If its borders were opened or communications with the rest of the world made easy, all kinds of unhappy consequences for the leadership may follow. Its enforced isolation makes comparison with the outside world impossible for most; the only basis of comparison for the average Albanian is the Albanian past (Part I, p. 567).

An alternative, or supplementary explanation of Albanian policies could point out, we might add, that its break with the USSR and its withholding of a blanket endorsement of Chinese policies followed closely in each case, the initiation by Albania's principal allies of a new policy of "opening to the West," a policy Albania apparently disapproves strongly. Albania's recent quarrel with China underscores this view.

In strong contrast to Albania, Romania and Yugoslavia is Bulgaria's economic strategy. The country's close political ties with the USSR have been matched by increased economic dependence on the Soviet Union, which in turn reinforces the political ties.

#### CHANGES IN THE ECONOMIC SYSTEM

In Yugoslavia, the early 1970's witnessed a growing disenchantment with excessive dependence on market forces, stemming from "worries about the apparent increase in economic inequality both among republics and among individuals within each republic and from concern over the perceived concentration of economic power in the hands of financial institutions, the managerial elite, and wholesale, retail and foreign trade enterprises." (Tyson, p. 946). The response has been:

Important constitutional changes altering the decision-making power of government authorities and enterprises;

The enterprise structure was changed to grant more independence to intra-enterprise units called BOALS;

A greater role was assigned to planning, and a new planning infrastructure was laid out by law;

New emphasis was given to social arrangements, as opposed to market considerations, on the basis of which fundamental economic decisions were formulated; and

The influence of the Party over economic policy was enhanced.

Despite the modifications, discussed in Part II of Tyson's essay, the Yugoslav economic system remains fundamentally unchanged: an imperfect market system based on the principles of social ownership of the means of production and workers' self-management in enterprise decision-making.

Romania has been characterized by relative lack of experimentation and change in economic organization (Jackson, p. 890).

### In Bulgaria,

The proposal that the market become the principal regulator of economic activity was buried by 1965, and since that time the main search has been for more effective administrative structures of management. The advocates of market socialism have left a certain legacy to subsequent mutations of the economic mechanism, in the form of more rational price system, an increased use of contracts to coordinate inter-enterprise relations, a substantial replacement of compulsory administrative controls by financial levers, and the strengthening of cost accounting and thus the autonomy of economic organizations. Despite this, the main thrust of reform has been to experiment with redistributing autonomy and control among the enterprises themselves [forming] large trusts known as State Economic Associations (SEA) and more recently [forming even larger] National Economic Complexes (Allen, p. 667).

A detailed examination of the Bulgarian system (Section 7) suggests that the Bulgarian economy has been subject to too much organizational change during the past ten years. At the same time, the record also indicates that the leaders are more concerned with establishing practical solutions than ideologically motivated ones. Reform proceeds by testing rather than a priori reasoning (in contrast with the Hungarian solution a decade ago). The most fruitful organizational experiments were carried out in agriculture (summarized below).

In Albania, 1965-66 marked the transition from a Soviet-type planning and management system to a specifically Albanian one in which ideological and moral incentives and outcomes ranked higher than economic results. Prompted by a relatively poor economic performance in 1961-65 (which Kaser and Schnytzer consider quite respectable in view of the difficult situation faced by Albania after the break with the Soviets) and the apparently economically motivated unrest among the population, a unique kind of decentralization of economic decision-making was carried out early in 1966. On the one hand, there was a significant reduction in the number of plan indicators—a conventional step in the East European setting—on the other hand, decision-power was devolved not to enterprise management but to the workers—which is quite unconventional. But the mobilization of workers was not intended, as in the Yugoslav case, to transfer effective control over enterprise resources to them, but to come up with “counterplans” to prevent managers from hiding capacity and drawing up inflated requests—an attempt to supplement hierarchical pressures on enterprise directors with Party-led pressure from below (Part II).

### ORGANIZATION AND POLICIES IN AGRICULTURE

Yugoslavia has a dual agriculture: a relatively small socialized sector accounting for 15 percent of the cultivated land, 7 percent of the population active in agriculture, and producing 25 percent of gross agricultural product—mainly industrial crops and grain—and a large private sector working the remaining land on small farms—providing mainly vegetables, fruits, and meat. Productivity in the private sector is alleged to be only one-fourth of that in the social sector. Strict adherence to voluntary collectivization, small size for private farms, lack of adequate investment resources, and unemployment in the

cities impose constraints on what can be done, so agriculture remains a problem sector (Tyson, Section V).

In Romania, agriculture was not touched by organizational reform; it is the only country outside Albania which has not dismantled the Machine Tractor Stations (MTS). Relative underinvestment in agriculture during the 1950's and 1960's makes the productivity of an active worker only about one-fourth of that of a nonagricultural worker (official data, see Jackson, probably biased by low valuation of agricultural products). Output performance during the 1960's was very poor (Montias, p. 868). In the 1970's, agriculture received a much higher priority and responded by showing significantly improved results.

In Bulgaria, 1956-66 was a period of steady growth, with output nearly doubling. This performance is attributable to a sharp increase in investment in the sector and a crop structure planned in accordance with the country's comparative advantage.<sup>41</sup> In the early 1970's, Bulgaria began to experiment with new forms of horizontal and vertical integration, creating so-called agro-industrial complexes by merging cooperative and state farms with agricultural processing plants. Some of these experiments are being adopted elsewhere, notably in Soviet Moldavia (Allen, Sections 8 and 9).

In Albania, where the collectivization of agriculture had been completed by the mid-1960's, agriculture has continually underfilled the plan; but it still made notable gains even after collectivization. The strong commitment of the Albanian leadership to be guided by ideological considerations in its economic decisions is illustrated by the fate of the MTS. Finding that the organizational separation of the state-owned MTS and group-owned collective farms was economically inefficient, but viewing the transfer of MTS to collective ownership as an ideological retrogression, it chose a uniquely Albanian solution: (1) in 1971 a so-called "higher-type" cooperative (so designating the economically strongest ones) was introduced and (2) each "higher-type" cooperative was given the exclusive service of an MTS. Thus, the agricultural machinery remains *de jure* state owned; but in terms of availability to the cooperative, there has been a *de facto* transfer (Part II, pp. 604-605).

#### POLICY ON PERSONAL INCOMES

In Romania during 1971-75, according to official figures, real disposable income per capita, excluding social consumption, grew 4.5 to 5.0 percent per year (see Jackson), real wages 3.6 percent per year, on par with the previous five years (Montias, p. 869). Given the rapid rise in investment and the growing share of accumulation in national income—officially estimated as 25.5 percent of NMP in 1961-65, 29.5 percent in 1966-70, and 34.1 percent in 1971-75 (Montias, p. 869)—the official figures on real wage income are probably upward biased. One reason may be the use of retail price index as a deflator which could underestimate the full extent of retail price increases (Montias, p. 869).

The real income of collective farmers inched up only 1 percent per annum in 1965-70 but increased rapidly during the 1971-75 FYP as

<sup>41</sup> For a detailed, empirical examination of Bulgarian strategy in agriculture and a comparison with that of Romania, see Gur Ofer, "Growth Strategy, Specialization in Agriculture, and Trade: A Comparison of Bulgaria with the Rest of Eastern Europe," in Paul Marer and J. M. Montias (eds.), "East European Integration and East-West Trade" (forthcoming, 1978).

the leadership became very concerned about the lagging performance in agriculture. Between 1955 and 1970, the agricultural versus non-agricultural gap in incomes rose rapidly, reaching 50 percent, "active" peasants earnings less than half of state employees. During 1971-75, there was an overhaul of the incentive system in agriculture: beginning in 1971, guaranteed monthly incomes were paid for special categories of farm work, and paid vacations, child and maternity benefits, sick leave, and more adequate pensions were granted. In 1975, a generalized system of wages for all collective peasants was decreed. The private sector in agriculture was stimulated by selective price increases, reducing taxes on income. In 1976, the tax on income from private farming and gardening was replaced by a final tax per unit of land used for such purposes (Jackson, p. 936). These measures caused a spectacular rise in peasant incomes after 1972; still, in 1975, peasant real incomes were only  $\frac{2}{3}$  of real wages of state employees, a figure that is not expected to improve by 1980 (Jackson, Table 32).

In Bulgaria, a major program was introduced in 1972 to increase the population's standard of living, reflecting in part a changed attitude toward economic causation:

Whereas previously it has been argued that increases in production were a precondition for increases in consumption, this argument was turned around and higher consumption levels were seen as necessary for increased labor productivity (Allen, p. 686).

Efforts to revive lagging agriculture caused incentives to encourage production on private plots. Income from this activity is no longer subject to taxes levied on speculative and unearned income. Pensions and wages have been raised gradually, virtually eliminating the gap between rural and urban incomes (Allen, p. 682).

In Yugoslavia, real personal incomes increased only 1.5 to 2 percent per year during 1971-75, held down by a combination of unexpectedly large increases in the cost of living index and a slowdown in the growth rate of workers' remittances from abroad. Future real incomes are slated to rise more rapidly. Private-sector agricultural incomes tend to be especially low in the Southern republics.

For Albania, no reliable income measures can be cited. It is interesting to note, however, the recent changes in the compensation in agriculture. Until 1971 the income of cooperatives was a combination of payments in cash and in kind and revenue from household plots. The size of the plot permitted had been reduced several times since 1961, but on each occasion the government offset the lost income by increases in procurement prices paid, reductions in the prices of goods bought by farmers, and most recently, the payment of state pensions to eligible farm members. In 1971, the system of remuneration was brought in line with practice elsewhere in Eastern Europe by introducing monthly advances of 70 to 80 percent of estimated income, the remainder to be paid at the end of the year on the basis of plan fulfillment (Part II, p. 604).

#### TRADE

Romania has exports estimated at about one-third of produced national income, a share that is not expected to rise by 1980. Until the early 1960's, Romania was a net exporter of raw materials and

foodstuffs and a net importer of manufactures. By 1973, it was exporting a slightly larger volume of manufactures, including chemicals, than it was importing; but, like all East European members of CMEA, it was running a very large deficit in industrial raw materials (Montias, p. 869).

In Bulgaria, the share of machinery and equipment in exports rose rapidly during the postwar period, reaching 41 percent by 1975, higher than for any other CMEA country except the GDR and Czechoslovakia. This was made possible by close links with the USSR and enthusiastic participation (not always reciprocated by the trade partner) in CMEA specialization projects. At the center of the country's industrial specialization is BALKANCAR, which produces fork lift trucks, lifting gear, cranes, hoists, and batteries. BALKANCAR exports over three-quarters of its production (70 percent to socialist countries) and accounts for 11 percent of Bulgaria's global exports (Allen, Section 12).

For Albania, Kaser has performed the painstaking job of reconstructing trade statistics from partner sources (Part V). One point is particularly worth stressing: the impressions that Albania has been relying exclusively on China is not borne out by carefully sifted evidence. During 1971-75, only 23 percent of Albania's export but 53 percent of its import trade was with China. CMEA members, principally the East European countries, took 49 percent of its exports and provided 27 percent of imports; the West (including Yugoslavia and the LDC's) supplied 27 percent of exports and took 20 percent of imports (Kaser, Table V-12).

#### POLICY ON WESTERN CREDITS

To what extent does an increased reliance on Western credits stem from an *ex ante* policy decision to make use of borrowed resources to accelerate growth or consumption or both, and to what extent is increased indebtedness the unplanned *ex post* outcome of unforeseen domestic developments (e.g., investment or consumption growing faster than planned) and international events (e.g., deteriorating terms of trade and Western recession hurting exports)? It is probably correct to state that every East European country's increase in hard-currency indebtedness was partly planned and partly unplanned, nevertheless, there appear to be significant differences among them.

Romania made planned use of large Western credits to accelerate its growth via large-scale Western machinery and other technology imports earlier than other East European CMEA countries. A rapid growth in trade with the West for the early 1960's was projected in 1958; and even before the shift was made, the Romanians began looking for credits to buy Western plants and equipment.<sup>42</sup>

In the case of Bulgaria, one has the impression that the rise in its indebtedness is largely the outcome of unforeseen domestic developments, such as the establishment of overly ambitious goals that are attainable only by extraordinary efforts. These efforts required bottleneck-breaking industrial imports from the West in the 1960s and machinery and consumer good imports in the 1970s. As Allen points out, efforts to balance the economy between 1973 and the first half of 1976 were inadequate; the economy seemed to be drifting

<sup>42</sup> E. M. Snell, "East Europe's Trade and Payments," p. 715.

while huge external debts piled up and consumer purchasing power ran ahead of supplies (p. 689).

In Yugoslavia, the recent increase in indebtedness seems to have been largely unplanned, resulting from external developments. Tyson stresses the balance-of-payments constraint on growth and the difficulty the country faces in restoring the foreign balance, given Yugoslavia's priority for growth and commitment to a decentralized economic system.

Albania is a special case: although it ran deficits during 1970-73 amounting to something like half the value of its small imports from the industrial West and obtained commercial credits from Italy (its major supplier among market economies), more recently it pledged not to rely on Western credits. Albania is believed to be the only government whose new constitution contains a legal prohibition against (presumably long-term only) external loans (Kaser, p. 1332). Credits from China are evidently OK.

### *B. Northern Tier Countries*

#### BROAD ECONOMIC STRATEGY

For the GDR, its ambiguous relations with the Federal Republic of Germany are an important determinant of its economic policy: "the GDR cannot help but feel that it is taking part in an unending economic race \* \* \* on whose outcome the very stability of the GDR may depend". (Keren, p. 721). The GDR cannot permit itself to fall far behind the FRG in consumption standards, a consideration underscored by the Polish riots in December 1970 which led to a reassessment of the consumer's place in East Germany's development policy.

This dilemma also conditions the GDR's relations with the Soviet Union and the rest of CMEA, where its potential weakness vis-a-vis the FRG gives it strength and leverage (Keren, p. 722).

For Czechoslovakia, the restoration of economic normalcy and control became the chief determinant of economic policy after 1968; the country seems to be characterized by an absence of any new economic strategy or policy initiative.

Hungary has been occupied with guiding its economy within the framework of its comprehensive economic reforms, with reasonable success, as is argued in the essay by Portes.

Poland is the site of one of the most notable new developments since 1970: adoption of a rather extreme version of import-induced growth as a development strategy, with a large part of imports financed by credits. Two environmental considerations, external and internal, played a large role in inducing this new strategy. The external one was the signing of a "normalization treaty" with the FRG in December 1970, followed by the Soviet-American detente of the early 1970's which created a climate conducive to reorientation toward the West. The internal consideration was the confrontation in December 1970 between the workers and the government following the rise in food prices. The government then acquiesced in the workers' combined demand of price freeze and substantial wage increases. This in turn ruled out an acceleration of investment growth based on internal resources—the strategy followed by Gomulka—and ushered

in the import-induced growth strategy of Gierek, initially planned on a moderate but realized in a rather extreme version, as discussed by Fallenbuchl (Parts I-III).<sup>43</sup>

#### CHANGES IN THE ECONOMIC SYSTEM

The *GDR* embarked on its own unique New Economic System (NES) in 1963-64. It was discarded at the end of the 1960s when the economy returned to the traditional Soviet-type economy fold. Keren summarizes the main features of the NES and illuminates in considerable detail the pressures which prompted the East German leadership to return to a more traditional planning and management system.

Czechoslovakia, after Husak's restoration of an authoritarian regime, terminated the earlier economic reform movement and gradually resurrected "the apparatus of central planning \* \* \* more thoroughly than it was thought possible" (Holesovsky, p. 714). Some argue, Holesovsky reports, that the resumption of economic expansion after the elimination of market-oriented reforms seems to support the anti-reformist position—an issue that is addressed also for East Germany by Keren. But the issue is not, Holesovsky believes, "does the system work?" but "how efficiently does it work compared to possible alternatives" (Holesovsky, Part III).

During the early 1970's, Poland experimented with limited economic reforms, but elements of it were introduced and often modified in a haphazard, internally inconsistent manner. As soon as there was an unfavorable change in the environment, there was an increase in the use of direct commands and intervention by central authorities. This reduced the autonomy granted to the so-called big economic organizations by the reform, although their autonomy had never been great. (See Fallenbuchl.)

Fallenbuchl concludes:

No serious economic reforms are envisaged for \* \* \* 1976-80. For the time being there seems to be no return even to the limited reforms which had been started in the first years of the decade. At least in 1977, the "new economic and financial system" will remain inoperative, the autonomy of the large economic organizations (WOG) will continue to be seriously limited, and the use of command directives rather than parametric steering will still be retained (p. 858)

For Hungary, Portes takes as his principal focus an analysis of the evolution of the country's "New Economic Mechanism" (NEM). Portes discusses how far the reformers' conception has been realized in practice and evaluates the economy's performance under NEM. He concludes that, overall, there was no slackening in the dynamism of economic growth. Real income increases accelerated as compared with the pre-reform period, and the record of controlling inflation has been good. But there has also been a notable lack of effective control over investments which, together with the worsening terms of trade, caused the unfavorable development in the hard-currency balance of payments (p. 781).

Very important is the detailed analysis of the status of the NEM since the widely noted "retrenchment" during 1972-74. He concludes that the essence of the NEM remains intact and that there

<sup>43</sup> See also S. Gomulka, "Investment Imports, Technical Change and Economic Growth: Poland 1971-1980," paper delivered to Conference of National Association for Soviet and East European Studies, Cambridge, UK, March 1977.

has been little further recentralization since 1973. Portes' final assessment is interesting:

This is itself remarkable in view of the extremely unfavorable impact from the foreign sector in 1974-75 \* \* \*. The fundamental success of the reforms is demonstrated by their resistance to a powerful set of forces, any of which alone might have brought back central physical allocation, obligatory plan targets and incentives based on them, and all else associated with the "standard system" of command planning (p. 788).

We might add a personal note to Portes' conclusion. If recent statements by Hungarian economists can be taken at face value, Hungary has made a tentative commitment to enlarge gradually the scope of the NEM by 1980, notably in the foreign trade and foreign exchange area.<sup>44</sup> This is because NEM is considered essential for implementing a new economic strategy, whose dual aim is (1) to restructure the economy toward sectors that are more productive and have good further potentials, and (2) to improve the effectiveness of Hungary's specialization in the world economy. These objectives require flexibility, adaptability, and enterprise initiative, requirements that are consistent with the mechanism of the NEM.

## VI. PROSPECTS

Two of the common, and in several countries the most serious, problems that remain to be solved are: (1) how to restore the economic imbalance created by the rapid rise in hard-currency indebtedness and other obligations, and (2) how to improve the efficiency of production, since productivity must generate a larger share of growth to compensate for slowdowns in the rate of growth of factor inputs—capital and labor. The two problems are interrelated.

Meeting foreign obligations and commitments—whether to the West for servicing the debt, to the USSR for investment participation or debt service, or to the LDCs in the form of new credits to finance machinery exports—involves a faster rate of growth of national income produced than national income domestically used. But additions to domestically available national income are an important source of new investment as well as for increased consumption. The latter is also, indirectly, a factor of production because increased consumer goods serve as incentives to elicit improved performance by labor.

A first approximation to the repayment burdens of East European countries on their hard-currency debts is their debt-service ratios (share of hard-currency exports devoted to interest and principal and thus unavailable to pay for current imports). At the end of 1976, the ratios of the East European countries were estimated as:<sup>45</sup>

Bulgaria.....	0.75	Hungary.....	0.37
Poland.....	.47	GDR.....	.30
Romania.....	.46	Czechoslovakia.....	.30

The debt service burden is reflected in the plans and recent policy changes of these countries. For example, in Bulgaria, in July 1976 the Central Committee Plenum adopted a new stabilization policy, mobilizing the entire party apparatus to solve problems of waste and over investment. The plans for 1977 project a rise in produced national

<sup>44</sup> Personal interviews, April 1977.

<sup>45</sup> Zoeter, *op. cit.*, appendix E. The hard-currency exports do not include invisible receipts. For countries like Bulgaria, the inclusion of invisibles would lower the ratio substantially.

income of 8.2 percent versus domestically utilized national income of only 4.5 percent (Allen p. 662).

Poland also plans to start repaying loans during the current FYP. Thus, while during 1971-75 utilized national income grew by 12 percent per annum versus produced national income by less than 10 percent, the plans for 1976-80 project a 4.8 percent versus 7 percent per annum ratio (Fallenbuchl, p. 857). The situation is similar in Romania, where utilized national income is scheduled to increase by 8 percent per year versus produced national income at more than 10 percent (Jackson, Table 9).

The East European countries plan to meet the hard-currency payment pressures by increasing export rather than by restricting imports. The question is whether exports can in fact be increased as rapidly as planned. This depends in part on economic conditions and commercial policies in the main Western countries, as well as on the exporting countries' ability to produce high-quality goods readily marketable for hard currency.

A slowdown in the growth rate of utilized national income (which could be quite substantial if imports have to be cut drastically) means that the growth rate of consumption will fall. Crucial for these countries' future prospects is an assessment of how the population will react. Soviet actions can amplify or cushion the expected slowing (or possible reduction) in the growth of consumption. Preliminary evidence suggests that the Soviets would lean, for political reasons, toward cushioning a decline by letting East European countries run up debts to be repaid in the 1980's or by reducing the amount of resources required to invest in projects located in the USSR. Both of these actions would free exports to the West.

On the problem of improving the efficiency of the economy; all countries face difficulties. The systemic and organizational obstacles to improved efficiency are well known problems. It must also be recognized that the change from a predominantly agricultural to a largely industrial society has been so rapid in the Balkan countries (and to some degree in Hungary and Poland) that most workers are only one generation or less removed from agriculture. Consequently, the quality of the nonagricultural labor force is poor, which may now be a major factor hindering improved productivity.

In many countries it is no longer possible to have a large-scale shift of labor from less productive agriculture to more productive non-agricultural sectors. Even in countries that still have a large agricultural work force with relatively low productivity, further large-scale reductions in the work force are constrained by (1) the unfavorable age and sex composition of the remaining work force; (2) small private plots too numerous in Poland and Yugoslavia, an arrangement not suitable to mechanization, but land consolidation is not now politically feasible; and (3) the amount of resources the state is willing to devote to improve agricultural productivity. Too rapid a reduction in agricultural work force without compensating investment causes output to lag which soon becomes a serious bottleneck in fulfilling export and domestic consumption plans.

To improve productivity, a renewed emphasis has been placed in all countries on technological innovation and on reducing the share of labor-material-and fuel-intensive products in output.<sup>46</sup>

<sup>46</sup> See analysis of the 1976-80 FYs of the East European countries and the USSR in United Nations, Economic Commission for Europe, Economic Survey of Europe, 1976, Annex.

In the short to medium run, numerous factors external to the economies of the East European countries will affect their performance and prospects. But in the longer run, their economic performance will be decided largely by their ability to overcome systemic limitations to productivity improvements.

#### APPENDIX. DERIVATION OF HUNGARY'S 1975 DOLLAR TRADE WITH SOCIALIST COUNTRIES

Hungary publishes trade statistics by groups of countries and also on the basis of the settlement currency used. Total exports and imports differ if recorded on a settlement rather than a partner country basis, as is shown in the tabulation below. This is because transport and related costs are recorded differently under the two concepts, as is shown in the tabulation (in million devisa-forints):

	1975 exports to—			1975 imports from—		
	Socialist (ruble)	Nonsocialist (dollar)	Total	Socialist (ruble)	Nonsocialist (dollar)	Total
By country.....	37,679	14,491	52,170	40,420	21,117	61,537
By settlement.....	33,109	19,750	52,859	37,285	23,315	60,600
Difference (by country less settlement).....	+4,570	-5,259	-689	+3,135	-2,198	+937

Trade recorded by partner country is valued at so-called "border parity." In exports (f.o.b. Hungarian border) this means subtracting from actual export proceeds the transport costs incurred by Hungary, in foreign exchange, from the Hungarian border to the actual delivery point. In imports (c.i.f. Hungarian border), it means adding to the actual contract price the foreign exchange cost of bringing the merchandise to the border. Trade recorded on a settlement basis shows the actual contract revenue on exports and actual contract cost of imports, whatever the location of sale or purchase, as specified in the contract.<sup>47</sup> Thus, exports are 689 million devisa-forints (\$80.1 million or SDR 58.7 million), or 1.3 percent larger if recorded on a settlement (contract) rather than a country (f.o.b. Hungarian border) basis, showing that Hungary incurred foreign exchange costs of that amount to deliver its exports to destination, as specified in the contract. Imports are 937 million devisa-forints (\$109 million or SDR 79.8), or 1.5 percent, larger if recorded on country (c.i.f. Hungarian border) rather than contract settlement basis, showing that Hungary incurred foreign exchange costs of that amount to transport its imports to its border.

These details help to determine the volume of Hungary's dollar-price-settlement trade with socialist countries, which in turn is the basis for understanding the difference between price indices calculated for socialist versus ruble-price-settlement and non-socialist versus dollar-price-settlement trade flows, presented in Table 7.

To estimate the size of Hungary's dollar-price-settlement trade with socialist countries, one should compare trade flows by country and by settlement that treat transport and related costs in an identical manner. Thus, in exports, the 33,109 million devisa-forint value includes a certain portion of the 689 million devisa-forint of total transport cost incurred by Hungary to deliver exports to a destination specified in the contract; whereas the 37,679 million devisa-forint value recorded on a country basis does not include transport costs beyond the Hungarian border. Because the socialist countries are located nearer to Hungary, on the average, than the nonsocialist countries, one would expect a more than proportionate share of the transport costs to be incurred on nonsocialist trade. If we assume, arbitrarily, that one-half of the transport cost is incurred in socialist and the other half on nonsocialist trade, then the trade flows recorded on country and settlement basis would be as follows (in million devisa-forints):

<sup>47</sup> Küklereskedelmi (1975), p. 7.

	Socialist (ruble)	Nonsocialist (dollar)	Total	Socialist (ruble)	Nonsocialist (dollar)	Total
By country.....	37,679	14,491	52,170	39,951	20,649	60,600
By settlement.....	32,764	19,406	52,170	37,285	23,315	60,600
Difference.....	+4,915	-4,915		+2,666	-2,666	
As percent of trade by country.....	13	33.9		6.7	13.1	

Thus, our best estimate is that, in 1975, 13 percent of Hungary's exports to the socialist countries (\$571.5 million or SDR 418.7) and 6.7 percent of its imports (\$310 million or SDR 227.1) from the same group were priced at current world market rather than CMEA contract prices.<sup>48</sup> Since most of these goods are comprised of primary products—energy, raw materials, and agricultural commodities—their current world price is probably higher, on the average, than CMEA contract prices. Accordingly, Hungary's export and import price indices in trade with socialist countries (which includes these higher-priced items) is higher than the corresponding indices in ruble-settlement trade (which excludes these items).

That Hungary's terms of trade with socialist countries is worse (by 3 percentage points) than in ruble-settlement trade, even though Hungary's exports contain almost twice as much of these higher-priced goods than its imports, suggests that the price differential was considerably larger in imports than in exports. This again, is expected because some of the above-quota deliveries are comprised of crude oil from the USSR.<sup>49</sup>

<sup>48</sup> For a more detailed discussion and estimates for 1971-75 (based on a somewhat different methodology), see M. J. Kohn and N. R. Lang, "The Intra-CMEA Foreign Trade System: Major Price Changes, Little Reforms," in this volume, Section V and Appendix 2; and Lawrence Brainard, "The CMEA Financial System and Integration," in Paul Marer and J. M. Mortias (eds.), *East European Integration and East-West trade*—table 2).

<sup>49</sup> In 1975 the USSR agreed to deliver to Hungary 760,000 tons of crude oil above the 6 million tons of planned shipments. If the price charged was, say \$60/ton, this item alone would represent \$45.6 million, or 20 percent of Hungary's dollar-price settlement imports. (The appropriate comparison is with the SDR rather than current dollar values because the devisa-forint/devisa-ruble exchange rate did not change after 1971.)

### I. THE CONTEXT OF ECONOMIC DEVELOPMENT

There can be no doubt that Albania is the poorest country in Europe; the only relevant questions are the degree of its poverty and the speed whereby its policy of socialist self-reliance is revolutionizing its economic prospects. The three decades since the Liberation of 1944 have witnessed not only faster development than at any time in its history but what its ruling Party of Labour rightly terms a socio-economic transformation from an agrarian to an agrarian-industrial and eventually to an industrial-agrarian nation. When the Albanian Communist Party (since 1948, the Party of Labour of Albania, hereafter PLA), took power at the end of World War II, it inherited a virtually feudal agriculture, with small-scale trade and crafts carried out within townships which had changed relatively little since the Turkish occupation. The poverty of the time was paralleled in some regions of Europe, but not as the characteristic of an entire economy.

Successive allies, Yugoslavia (1944-48), the U.S.S.R. (1964-61) and China (since 1961) have extended economic assistance. During the period of the Five-year Plan for 1971-75 it is estimated in this paper that Chinese assistance was worth \$485 mn on a cumulative import bill of \$1,238 mn, that is two fifths. In 1970 estimates described below put external aid as adding 8 percent to gross territorial product to yield a gross domestic or gross national product of \$693 mn. The main contributor to economic growth has been a determined mobilization of domestic resources; save only for a few early years, "self-reliance", owing something to the Chinese model but much evoked by the PLA, has been the watchword.

# Albania and Kosovo Administrative Division with District Populations, 1973

Population of districts in thousands

No estimate appears to have been made in any source of the Albanian national accounts and those which appear in this section must be regarded as highly tentative.<sup>1</sup> The conversion of domestic prices into a Western currency is fraught with uncertainties, but if the magnitudes are in any reasonable approximation to reality, the level of poverty which still remains despite three decades of impressive effort, is evident from a GNP per capita in 1970 of \$350.

But Albania is not the sole homeland of the four million Albanians in the Western Balkan peninsula: three-fifths inhabit the People's republic, but two-fifths occupy the Kosovo Autonomous Province of Yugoslavia. It was on the latter territory that modern Albanian nationalism was born as the League of Prizren in 1878. Albanian independence was proclaimed in 1912, when four years of sporadic uprisings against the Turkish rulers coincided with the Balkan War (1912-13). Although recognized by the Great Powers, Albania fell prey to occupation by both sides during World War I and the postwar boundaries restricted Albania to its present boundaries while the newly-created Yugoslavia incorporated Kosovo. The Italian invasion of April 1939, followed in 1941 by the German defeat of Yugoslavia, facilitated a reunion, but one founded solely on the force of alien occupation.

The Albanian Communist Party was founded under that occupation in November 1941 and the cooperation of its resistance army with the Yugoslav Partisans made respect for the prewar frontier inevitable when both were victorious. Although the federal constitution with which Yugoslavia was endowed by its dominant Communist Party did not, however, separate Kosovo from the Serbian Republic, Albanian union with Yugoslavia as a federated republic would have embraced an enlargement to include Kosovo.

Yugoslavia's break with the Soviet Union, whose part Albania took, in 1948 ruptured the ties between Kosovo and Albania and was the pretext for the imposition of Serbian police rule on Kosovo to inhibit any separatist or dissident movement.

The year 1966 marked a most striking change in the government of the two Albanian territories. The dismissal of the Yugoslav Minister of the Interior, Aleksandar Ranković, was followed by concessions to the Kosovar nationalists, whose agitation had been increasing in the early sixties and which now reached a peak in 1968. The new Yugoslav Constitution of June 1971 set the seal on the trend to recognition of Kosovar nationality (the Autonomous Province adopted the Albanian flag as its own) but fell short of Republican status. The introduction of a new policy in Albania in 1966 was still more abrupt, for the Cultural Revolution was propagated by the PLA, principally to break the hold of bureaucracy, religion and survivals of feudalism. The present paper cannot but take that year as the dividing line in government and party policies.<sup>2</sup>

<sup>1</sup> One of the authors of this study, in the context of an exercise in prognosis, made a sketch estimate in 1966 of Albanian product in 1967 and 1970 (later published in P. Wiles ed.), *The Prediction of Communist Economic Performance*, Cambridge, 1971, p. 93).

<sup>2</sup> The principal studies in English, from considerably differing standpoints, of this period in a long-run context are Ash, *Pickaxe and Rifle*, London, 1975; A. Logoreci, *The Albanians*, London, 1976; R. Marmallaku, *Albania and the Albanians*, London 1975 and N.C. Pano, *The People's Republic of Albania*, Baltimore, 1968. The three latter are Albanian, a British citizen resident in the UK, the second in Yugoslavia and the last a United States citizen.

But what is more significant for Albanians as a nationality is the growth over the past decade of contact between Kosovo and Albania. The new University of Prishtinë has become a centre of Albanian culture and deliberate efforts are being made by the Kosovo authorities to adopt the present standard form of the Albanian language.

The division of Albanian into a northern dialect, Geg and a southern, Tosk, effectively at the river Shkumbi, seems to reflect some pre-historic linguistic frontier and certainly has been long exhibited in differing popular characteristics. The Gëgs were scarcely ever subject to Ottoman rule, maintained a patriarchal mode of life and subjected themselves to the blood feud. The Tosks settled on large estates, and took more readily to education and to urban life. The majority of the early PLA leaders, including Enver Hoxha, before the war a graduate student of a Belgian University and a teacher at the French Lycée in Korçë, are Tosk and the standard language is based on Tosk. The Gëgs in Albania have inevitably adopted the standard tongue (though using much Geg informally) and since 1966 the trend to standard Tosk has been clearly patent in Kosovo.

The ethnic background to the two Albanian territories serves to underpin the economic comparison that is made in this first section between the two. But the relativity is helpful on a further criterion, namely that Albania has embraced an economic system that impells the enterprise manager to conform to central directives by organized worker pressure; it is a command economy on the Stalinist model adopting several distinctive Albanian practices. On the other hand Kosovo shares with the rest of Yugoslavia the procedures of worker self-management which were innovated by the Yugoslav League of Communists in 1950 precisely to differentiate their economy and ideology from Stalin's. The economic reform of 1965 (with the political liberalization that followed the dismissal of the Minister of the Interior) endowed the enterprises with a market framework for decisions. No trustworthy comparison can be made on the basis of existing statistics of the relative economic efficiencies under which the two groups of Albanians live, but the different economic systems must at some time attract more detailed study. Being the first thorough examination of the Albanian economy since that of the United Nations Economic Commission for Europe in its *Economic Survey of Europe in 1960*, and the first to appear in the Congressional Compendium, it is of necessity tentative.

### A. *The Political Environment*

Political developments in Albania have received some attention in the West, particularly Albania's role in the Sino-Soviet split and blow-by-blow accounts of purges within the upper echelons of the PLA hierarchy.<sup>3</sup> Unfortunately, however, no attempt appears yet to have been made to relate political and social variables to the country's economic development. In the following discussion an attempt is made to briefly fill this gap by outlining some of the non-economic factors which must be considered in evaluating the ensuing economic analysis.

<sup>3</sup> See, for example, Pano, op. cit. and W. E. Griffith, *Albania and the Sino-Soviet Rift*, Cambridge, Mass., 1963.

Since November 8, 1941 when the Albanian Communist Party was formed, its First Secretary (originally Secretary-General) has been Enver Hoxha and at almost all times since the Chairman of the Council of Ministers Mehmet Shehu, and Hysni Kapo, the Party Secretary for ideology, have been members of the Politbureau. Of the East European states, only Yugoslavia has a similar record of continuous leadership. It is no exaggeration to argue that almost all Albanian economic policy since World War II has been initiated by the ideas of these three men. Thus, more often than in any other East European economy, a speech made by a member of the Party leadership has led almost immediately to perceptible changes in policy. For example, in his report to the Sixth Congress of the PLA in November 1971, Enver Hoxha suggested that mathematical techniques would be useful in raising the "scientific content" of economic planning. This speech was followed by numerous articles on the subject in the Albanian press and, between 1972 and 1974 a wide variety of mathematical economic text-books were published by Tirana State University.

On the other hand, this is not to suggest that the Albanian population determines its behaviour on the basis of norms dictated by the Party leadership. Indeed, the closed nature of Albanian society and the absence of explicit economic debate in Albanian publications renders the distinction desired and actual outcomes extremely difficult to make. Thus it is impossible to determine the precise extent to which, for example, the schemes for worker participation and cadre circulation discussed in section II have actually been put into practice. However, it does not seem reasonable to conclude that none of these policies were ever implemented, there being elements of the social environment which suggest that certain ideologically-motivated campaigns might enjoy more public support than similar measures elsewhere in Eastern Europe. Thus, the statement is often made in socialist economies that certain construction work was undertaken "voluntarily" by students in their spare time. In evaluating the validity of this claim in the case of Albania it must be recalled that the sale of young girls into betrothal by their parents was a common feature of pre-war Albania. The PLA has devoted considerable space in the press and effort through the school system to convince the youth that marriage should take place on the basis of mutual love and that this can only develop if teenagers are permitted to mix socially without significant interference from parents. To facilitate this arguably popular situation—and it must be noted that well over 60 per cent of the Albanian population is under thirty years of age—the PLA organized the transport of hundreds of Geg girls from the more conservative northern regions to work on the Fier-R rogozhira railway site with Tosk youths from the south. Under these circumstances it seems likely that the term "voluntary" is appropriate.

The backwardness of the past and the linguistic and geographic isolation of Albania are further factors likely to lead to popular support for the PLA's policies. Thus in 1945 over 80 per cent of the population was illiterate, whereas by 1972 every third citizen was enrolled in some kind of educational institution.<sup>4</sup> The low level of

<sup>4</sup> Marmullaku, *op. cit.*, p. 78.

economic development has already been noted and thus, when the PLA argues for support for its policies on the basis of its past record, it would be difficult to dispute its achievements. The country's isolation only serves to facilitate this situation, the only basis of comparison for the average Albania being the Albanian past.

The PLA's implied eagerness for popular support must be contrasted with the steadfast determination of the leadership not to tolerate dissent within the party. Albania is probably the only country in Eastern Europe in which officials of high rank may incur loss of life when they are dismissed. The economic implications of recent purges are discussed in section IV: suffice it to note here that statements such as the following made at the Seventh Congress of the PLA in November 1976 leave little doubt as to the victims' fate:

The Party and the dictatorship of the proletariat hit them with an iron fist and threw them into the dustbin, where all the traitors to the revolution belong.<sup>5</sup>

Concomitant with the elimination of opposition is the leadership's policy of promoting young people to high government posts, officials presumably being free from Soviet and other undesirable influences from the past and supporters of Enver Hoxha. The elevation of two women, both under forty and without any previous experience in government, to the posts of Minister of Agriculture and Minister of Education in April 1976 provide good examples of this policy. Enver Hoxha like Marshal Tito in Yugoslavia is clearly concerned that his policies should live on after him.

Finally, mention must be made of the most important political factor in the determination of Albania's external economic relations and her industrial policy of self-reliance, nationalism. Thus, whereas Hoxha in his 250-page report to the Seventh Congress criticized many deviations from marxism-leninism, he never referred to nationalism. The following extract from Shehu's report suggests the reason for the omission:

Should we permit foreign armies to be based or deployed on our territory? Never! They will say that we are small and cannot resist. That is what the imperialists and capitulationists have always said of small nations. . . . In these conditions, as comrade Enver Hoxha put it over 16 years ago, "cursed be our mothers' milk, cursed be the bread the Party and people feed us with, if we do not defend the interests of our people."<sup>6</sup>

The PLA leadership has consistently used the argument that Albania is surrounded by enemies bent on her destruction to justify high rates of accumulation for industrialization stringent import controls and the policy of self-reliance (the combination of which is discussed in section IV).

### *B. International Comparison*

A novelty of this paper is the reconstruction of a national accounting framework for Albania and a conversion of the main aggregates into United States dollars. Both the exercise in composing an account and the use of the exchange rate for non-commercial transactions are tentative, but as some verification can be found in comparison of the aggregates with those for the Kosovo Autonomous Province of Yugoslavia, an area predominantly inhabited by Albanians who settled there during the long Turkish occupation of the Balkans. The rela-

<sup>5</sup> E. Hoxha, *Report to the Seventh Congress of the PLA*, Tirana, 1976, p. 8.

<sup>6</sup> M. Shehu, *Report on the Sixth Five-Year Plan, (1976-1980)*, Tirana, 1976, pp. 112-113;

tivities in values per capita between Albania and Kosovo are in their turn subject to a rough verification by a comparison of physical production per capita and by comparisons of retail prices in Albania, Yugoslavia and the United States.

It is appropriate to bring together at the outset a discussion of the rate of exchange, since the approach here adopted of comparing national products depends on the conversion of leks into dinars; insufficient data in physical terms are available from Albania for foreign prices to be applied to national quantities. The rate between the Albanian lek and the dollar is determined by the State Bank of Albania at its own discretion. No leks may be exported or imported and foreign transactions or remittances are denominated in the partner's or a vehicle currency. The pre-war Albanian franc had been one of the strongest currencies in Europe, with sound gold backing, but had depreciated during the occupation. It was replaced by the lek in 1947, which from its inception has been inconvertible. The rate used to compile trade returns is the 'official' rate shown in Table 13 of the paper on Albania in Part III and bears no direct relation to the purchasing power of the lek at home. The 'non-commercial' rate chiefly serves tourism and remittances and is intended to reflect mainly the prices of goods and services bought by tourists. The non-commercial rate ruling throughout 1970 was 12.50 lek to the dollar and the very few food prices available in published Albanian sources show this not to be unrealistic:

[Prices per kilogram in 1970]

	Leks in Albania	Cents in United States	Leks per dollar
Bread.....	2.0	53.6	3.73
Flour.....	3.7	26.0	14.23
Rice.....	8.0	42.1	19.00
Sugar.....	8.0	28.7	3.48

Source: Table III-8 and Statistical Abstract of the United States.

The spread around the rate is expectedly wide and, with no information on Albanian weights, it is impressionistically satisfactory. A second check on the appropriateness of the 12.50 rate may be found in a very rough estimate by one of the authors of 15.50 leks to the dollar for 1966 prices.<sup>7</sup> 1971 prices used for some of the entries in the present estimate of national accounts were 12 per cent below the 1966 prices which were effective until 1966,<sup>8</sup> when the industrial price index was 8 per cent below that of 1971. The lower bound of the 1966-prices estimate was 13.50 leks to the dollar,<sup>9</sup> which would extrapolate to 12.50 leks for 1971 prices (if industrial prices were on trend). As retail prices may have fallen a little faster (see 1956 and 1970 prices in Table III-8), the 1966 and 1970 estimates seem compatible.

The comparison of the national accounts with the Kosovo Autonomous Province also raises the issue of the reflection of the purchasing power of the Yugoslav dinar in the official exchange rate, which, as it happened, was 12.50 to the dollar throughout 1970. The rates diverged

<sup>7</sup> The estimate of the degree of over-valuation of the Albanian lek can only be guessed at within wide limits'. (Kaser, *loc. cit.*)

<sup>8</sup> See Appendix I, section C for the deflator.

<sup>9</sup> See original paper by Kaser, *Analyse et Prévision*, November 1967, (Vol. IV, No. 5), p. 766.

at the devaluation of the dinar to 17 to the dollar in December 1971. The Organization for Economic Cooperation and Development (OECD) appears to use the official rate to render the Yugoslav GNP into dollars, but has not published a dollar figure for 1970.<sup>10</sup> It has in many reports published a value per capita for 1969 (\$561) and for 1971 (\$760): the mean of those years (\$660)<sup>11</sup> compares with the Yugoslav official estimate of 7,658 dinars per capita, which would be 11.60 dinars to the dollar.

A much higher purchasing power of the dinar in relation to the lek at the cross-rate to the dollar is indicated from a comparison of retail prices in Table III-8. The arithmetical average of the six prices which have been found for the two currencies shows that in 1970 the dinar bought exactly twice as much as the lek. The smallness of the sample and the uncertainty of precise comparison precludes any exact measure of relative purchasing power, but retail prices are a poor reflection of all prices, since Albanian retail prices bear a heavy turnover tax, which partly subsidises capital-good prices, while Yugoslav fiscal reliance is heavily on across-the-board taxes on enterprise profits and on worker dividends. The validity of the dollar rate for the dinar may also be brought into question. Of the foods shown in Table III-8, the dollar in terms of bread was 3.54 dinars, flour 5.00 dinars and sugar 9.76 dinars.

The calculation applying 12.50 leks to the dollar, shown in Table I-1 and explained in the Appendix, puts Albanian gross domestic product (GDP) in 1970 at \$693 mn. The United Nations System of National Accounts (SNA) allows only factor income from abroad to be counted as the aggregate additional to gross domestic product (GDP) which constitutes gross national product (GNP). It seemed appropriate therefore to use the concept of gross territorial product (GTP) to define GDP less the import deficit (Table I-1). A GTP of \$693 mn was supplemented in 1970 by an excess of imports over exports of \$55 mn to constitute a GNP or GDP (since there was no factor income from abroad of \$748 mn. At a mean population that year of 2,135,600, the per capita GNP/GDP was \$350.

In world terms, a GNP of \$350 per capita was well below those of other European countries, \$613 for Yugoslavia, \$653 for Portugal, \$682 for Malta, all—like Albania—in poorer Southern Europe. But it was in line with a per capita GNP in 1970 of \$361 for the Philippines, \$362 for Brazil and \$384 for Iran. A more telling comparison is, however, with the neighbouring Kosovo Autonomous Province in Yugoslavia, which had a GNP per capita at the prevailing exchange rate of only \$205 per capita.<sup>12</sup> The composition of NMP in Albania and in Kosovo (Table I-2) is in domestic currency units but as the rate to the dollar was 12.50 dinars and 12.50 leks, they are meaningful in terms of each other in prevailing exchange rates. The disparity of price structures in Kosovo and Albania must be stressed at the outset<sup>13</sup> as are the tentative nature of the Albanian

<sup>10</sup> The United Nations, *Yearbook of National Accounts Statistics*, 1971, Vol. III, does not give dollar estimates for Yugoslavia or for any planned economy.

<sup>11</sup> A value of \$660 per capita is also shown as the product of 1969 GNP per capita in the OECD estimate and the increment of 18.0 per cent in 1970 in the official Yugoslav (*Statistički godišnjak* 1976 pp. 101, 137) shows the mean 1969 population at 20,371,000 and GNP as 131.96 bn dinars.

<sup>12</sup> GNP arising in Kosovo was 2,907 mn dinars in 1970 (*Statistički godišnjak*, 1975, Table 204-3) or 2,383 dinars per capita, for a population of 1.22 mn; for a population of 20,527,000, Yugoslav GNP was 157,207 mn dinars (*Statistički godišnjak* 1976, Table 106-1), or 7,658 dinars per capita. Hence Kosovo was 31.3 per cent of the national average per capita. The dollar equivalent for Kosovo is thus 31.1 per cent of \$660 per capita, or \$205.

<sup>13</sup> Turnover tax in 1969 for example brought in 2.14 bn leks from a retail turnover of 7.47 bn.

aggregates. The two international bodies of which Albania is a member and which seek to publish comprehensive national accounting data rigorously eschew any statement on Albania, save the rare official indexes. Thus the United Nations *Yearbook of National Accounts Statistics, 1975* (1976) publishes only a breakdown of NMP as index-numbers (1960–1969, with later years blank) and socialist-sector gross fixed capital formation (in value for the same period). Its *Statistical Yearbook* omits Albania from all international comparative tables. The Secretariat of the United Nations Economic Commission for Europe similarly left Albania out of its estimates of gross domestic product of most European countries in a common currency in its *Economic Survey of Europe in 1969*<sup>14</sup>—or of the net material product which it employs to weight its annual composite index of national income produced in East Europe; it also excludes Albania from its aggregate industrial index.<sup>15</sup> The Yugoslav Federal Board of Statistics publishes detailed annual breakdowns of its national accounts for each of the constituent republics and the autonomous provinces of Serbia (of which Kosovo is one); because it adopts both the SNA of the United Nations and the NMP basis as utilized in Albania, its data furnish a valuable standard of comparison. Although as already mentioned the lek and dinar were by coincidence at par in purchasing power in 1970, it is less the magnitudes that are of interest than the relativities.

The *caveat* is of particular importance in assessing the origin of material product. The percentage generated in construction and transport is the same, but, as would be expected in a small-scale market economy, even a socialist one, trade and catering contributes more in Kosovo than in Albania (private employment in small hotels and restaurants is permitted in Yugoslavia). Transport and trade are the only two branches in which Kosovo output per capita is close to that of Albania.

The principal divergence in structure arises between agriculture and industry. Agricultural production per head of population in Kosovo would, on the estimates of Table I-2, be only 70 per cent of that in Albania, but contribute a larger share of material product because of its much smaller output of industry per head. Industry provides 58 per cent per capita in Kosovo of that which it does in Albania. The Yugoslav statistics show a breakdown between industry and handicrafts (870mn dinars and 98mn respectively) but no corresponding estimate can be made for Albania, nor do either separate mining from manufacturing. In considering the industrial share of 42.4 per cent for Albania with 37.2 per cent for Kosovo the possible effects of price ratios must be borne in mind: detail of Albanian prices is however far too sparse to attempt any repricing, but it could be that in a market economy with an independent peasantry (collectivization was abandoned in Yugoslavia in 1950) farm-gate prices are higher than those for compulsory deliveries from cooperative farms in Albania, both sets of prices judged in relation to industrial producer prices.

It would also be a feature of Albanian management to understate depreciation in relation to Yugoslav practice, with the implication

<sup>14</sup> Initially presented in *Survey*, Part II, chapter I, text table, p. 1; for subsequent use (and continued omission of Albania) see *Survey*, Part II, chapter I, Table 1.1.

<sup>15</sup> *Economic Survey of Europe in 1972*, text-table on p. 54.

that gross material product (GMP) is a more reliable criterion. Per capita GMP in Kosovo in 1970 was 68 per cent of that in Albania. The divergence on depreciation practice could arise on the overestimation of the length of asset life (familiar procedure in a centrally-planned economy) and the relative disregard of obsolescence as a factor in a decision to scrap, taken with the virtual absence of authority on the part of the enterprise director to re-invest his amortization allowances (see text-table in Section II). Under the market syndicalism of Yugoslavia, depreciation would tend to be calculated so as to yield the replacement value when the asset was withdrawn in face of competitive factor pricing, thus shortening expected asset life and calculating amortization with some reference to the cost of replacement (against original value in Albania). The nature of the two economies also shows itself in the addition of inter-enterprise transfers to yield gross social product. Table I-2 deliberately shows these flows as additions to GMP, not as part of GSP, as in Albanian (and general East European) practice because the size of GSP depends not only on real economic activities but also upon their organization. It is in that organization that the interest of the comparison lies, for more transfers take place per unit of value-added in Albania than in Kosovo. Partly this must be due to the simpler structure of the poorer agrarian economy, viz. Kosovo peasants are more self-sufficient than Albanian collective farmers, that Albanian industry has a higher degree of fabrication than that in Kosovo and, possibly, that the use of global industrial output as an indicator for Albanian enterprise plan fulfilment encourages use of purchased inputs more than under worker-management, which seeks to maximise the dividend per employee of value added (see chapter by Laura Tyson). Whatever the cause, such duplicative flows add (on these tentative estimates) 83 percent to Albanian GMP but 101 per cent to that of Kosovo.

The contribution made by the import surplus, nearly all from China, shows itself, in a large but uncertain addition in domestic prices to Albanian NMP produced, though only 8 percent to GTP in foreign-trade prices if trade is valued at 5 leks to the dollar and GTP at 12.50 leks to the dollar. For Kosovo an order of magnitude is suggested by allocating the Yugoslav import surplus *pro rata* to its population. This is not unreasonable as a note to Table I-2 points out, since the finance of Yugoslav central funds to the Kosovo Provincial budget was 396 mn leks in 1970 and an income to the private sector from emigrants' remittances and tourism<sup>16</sup> (although the Albanian minority seeks relief from local underemployment mainly elsewhere in Yugoslavia, rather than abroad) and of equity investment to the self-managed enterprise sector is to be added (though only an export figure is published). On this concept of an import surplus, 22 per cent was added to Kosovo GMP in 1970. In both cases the balance of payments on invisibles is neglected: the external commercial relations of Albanian and Kosovo enterprises are each modest, Kosovo by itself has no diplomatic relations and although Albania has diplomatic relations with over 60 countries, the cost of its embassies and consulates is unlikely to represent a major net outlay over foreign representation in Tirana.

<sup>16</sup> Workers' remittances brought \$350 mn in 1970 (at the Census of March 31, 1971 682,300 workers were abroad), and tourism \$250 mn (4.7 mn tourists visited Yugoslavia that year). There was no emigration from Albania and only a handful of tourists visited the country.

The summation of NMP produced and the import surplus yields NMP distributed, of which (as Table I-2 shows) consumption takes a higher share in Albania than in Kosovo. The difference could all be due to classification, since defence spending is counted in Yugoslavia as consumption but divided in Albania between that and accumulation (military hardware is an inventory in the NMP system). This divergence of practice complicates the assessment of monetization. Albanian auto-consumption (mainly consumption of homegrown food by farmers but including some craft work and repairs) was about 30 per cent of the 'consumption fund',<sup>17</sup> but Yugoslav statistics do not show sufficient detail for Kosovo: the aggregate share of non-monetized consumption in Yugoslavia as a whole was 15 per cent in 1970.<sup>18</sup>

Defence outlays taken together, whether nationally divided between consumption and accumulation, and defined as outlay, defined as such in the budget, were 4.3 per cent of GNP in 1970. This was much the level of other Balkan states, e.g. Greece 4 per cent, Turkey 3.7 per cent before the Cyprus dispute (though these had risen to nearly 7 and 9 per cent respectively by 1975),<sup>19</sup> but a trifle below Yugoslavia (exactly 5.0 per cent of GNP that year).

A comparison of physical indicators of production made in Table I-3 puts an altogether different picture of the relation of Kosovo to Albania. In per capita terms the Kosovar produces more of ten of the indicators there shown, while the Albanian has the lead in three. The energy inputs may not much differ: the much higher coal production in Kosovo is balanced by the large oil output of Albania; the very considerably electricity production of Kosovo is necessitated by an aluminium industry, which has no counterpart in Albania and without investigation of the respective shares of hydropower an energy balance cannot be computed. Exports are about the same, although Kosovo sales to other parts of Yugoslavia are not accountable. Certainly the figures in physical units do not justify as wide a disparity as in the GNP computations and could well demonstrate a reasonable economic parity between the two groups of Albanians.

### C. Manpower

Defence and internal security was estimated by Western authorities to occupy 53,800,<sup>20</sup> while civilian employment was 392,000 on official statistics.<sup>21</sup> No other occupational data have been published since the returns of the Census of October 2, 1960. Although the total population at the July 1, 1969 Census was published, no detail thereof ever appeared.

Table I-4 shows the distribution of the gainfully-occupied at the 1960 Census (military conscripts being assigned to their civilian job group or expected occupation). The considerable proportion then engaged in the private sector has by now largely disappeared, although (as discussed in Section III) the combination is persistent of side-line activity with membership of a cooperative or employment in a state

<sup>17</sup> This is the ratio to personal consumption quoted by *Statistike ekonomikë*, Tirana, 1971, p. 434; Appendix Table II puts it at 28 per cent in 1970.

<sup>18</sup> *Statistički godišnjak*, 1975, Table 106-1.

<sup>19</sup> *Financial Times* (London), 30 November 1976.

<sup>20</sup> *The Statesman's Yearbook*, 1973/74, p. 733.

<sup>21</sup> 30 vjet . . . , p. 41.

enterprise. The official national accounts show the extinction of the private sector as a contributor to NMP in 1967 (from 11.9 per cent in 1960 through 7.2 per cent in 1966). In retrospect 1966 must have been a year in which the private sector of agriculture was being favoured, for whereas individual peasants had received no government loans the previous year, they were given 5,194,000 leks in 1966 (against 52,874,000 to cooperatives) and 271,000 in 1968; the next year the recorded total was a mere 4,000 leks and by 1969 nothing was being given.<sup>22</sup>

As the private sector was eliminated, those occupied entered state employment or maintained their rural occupations as farms were collectivized. As Table I-4 shows state blue-collar employment had more than doubled (2.17-fold increment 1960-73) by the time even this minimal manpower series ceased to appear, and white-collar employment had risen nearly two-thirds (64 per cent rise 1960-73).

The reserves upon which industrialization could draw over the past fifteen years are indicated by the low female participation rate (Table I-5). At the 1960 Census 55 per cent of women of working age (defined as 15-54)<sup>23</sup> were not gainfully employed, though only 11 per cent of the men (defined as 15-59) were in that position. Even more manpower potential is provided by rapid demographic growth. The last official returns put the working-age population at 1.16mn in 1973 and a United States Government projection puts that class at 1.31mn in 1975 on a wider age spread (both sexes 15-64) rising to 1.54mn in 1980. The current five-year Plan gives, however, no employment target for 1980.

The rapid increment of the population in Albania is the factor of production upon which Albania has been able to, and can continue to, rely. As Table I-6 sets out, the 22.5 per mile natural increase of today, while below the peak of the sixties, is among the highest in Europe. A projection of the Secretariat of the United Nations Economic Commission for Europe chooses a gross reproduction rate falling from a 1970-75 estimated experience of 2.37 to 1.28 in 1995-2000 (i.e. the number of female children born to women during their reproductive lifetimes if a given set of age-fertility rates remain in effect). The United States Department of Commerce puts its "medium" projection at a gross reproduction rate of 1.50.<sup>24</sup> With a declining mortality which extends life expectancy at birth from 67.2 years to 70.3 years for males and from 69.9 to 73.4 for females, the former projection puts the Albania population in the year 2000 at 4.3 mn (a 96 per cent increment over three decades). The latter, which shows a rise in the median age from 19.5 years in 1975 to 24.1 in 2000, gives Albania 4.14mn population by the end of the century.<sup>25</sup> No other country even remotely approaches a demographic dynamism of Albania, Albania, although, within a Yugoslav projected growth of 26 per cent ("medium" projection) growth in Kosovo will be close to the Albanian. The average growth for East Europe between 1970 and 2000 would, on the ECE estimate, be 18 per cent (21.5 for all of Europe and the USSR).<sup>26</sup> But from 2.1 per cent of the population of East Europe in 1970, Albania will rise to 3.4 per cent in the year 2000.

## THE NATURAL ENDOWMENT

Rapid population growth has doubled the number of Albanians per square kilometer during the period of central planning: from 42 in 1950 to 87 in 1977. The area of the country is 28,748 sq. km. of which in 1969 14 percent was quite unproductive, and 43 percent is under forest. The land under agricultural use comprises 17 percent arable, 3 percent under plantations (mainly vineyards and olive groves, but increasingly citrus orchards) and 22 percent a meadow and pasture. As Table I-6 indicates, the latter have been ploughed up over the two decades, in the second of which a new arable-land campaign was strongly promoted in the highlands. In the earlier postwar period considerable investment in drainage changed the use of the malarial coastal plain from seasonal grazing to intensive cash cropping. Although the First Five-years had ambitiously sought self-sufficiency in grain, the elimination of cereal imports was not attained until 1976, but the achievement was worthy enough. When Albania was a member of Comecon, it was encouraged to concentrate on fruit-growing—a highly valued produce in a group of countries mostly with harsher climates, and—it was alleged when the Elbasan Metallurgical Works, Albania's first, was opened in 1976—to export its iron ore to Czechoslovakia. Once it had launched itself on an independent road, the exploitation of its mineral wealth as much for domestic fabrication as for sale abroad became the watchword.

The mountains of Albania are rich in metalliferous ores. Chromite occurs widely, copper is mainly found between the Drin and Mat valleys in the centre of the country and iron-nickel ores in Pogradec, in the Drin valley and to the west and south of Lake Ohrid. Coal deposits are of poor quality, but the modest prospects for oil were transformed in 1957 with the opening of the Cerrik field, where asphalt bitumen has been exploited since classical antiquity. Hydroelectric potential is considerable and estimated at 2.5 mn kW.<sup>27</sup>

Exploitation of the mineral resources, adequate cutting of forests and supply and marketing for agriculture have all been hindered by the rough terrain in all but the littoral, and opening up has awaited proper communications. Under the Italian occupation a network of motorable roads was begun and work started on the country's first railway. The latter was completed by the present administration and has been extended annually.

Railway building and land melioration works have served *par excellence* the application of manpower to natural resources, for the youth projects of thirty years (but particularly recent) as already observed, are seen by the PLA not only as economic tasks but as political campaigns to bring rural youth, especially girls, out of the restrictive environment of the village and to enthuse townchildren with a zest for patriotic labour.

<sup>1</sup> As noted in text, conversion rates to the U.S. dollar are 12.50 dinars and 12.50 leks, so that national units may be directly compared.

<sup>2</sup> Includes for Albania price differential on internationally traded goods and errors in compilation of accounts; for Kosovo estimate of current and capital flows from other parts of Yugoslavia and from abroad.

Source: Albania from table 1-1, except for the subdivision of "other productive" branches which was computed from the index numbers of net contributions to NMP from 1955 to 1960 in Vjetari statistikor, 1967-68, p. 107 spliced to that from 1960 to 1969 in *ibid.*, 1969-70, p. 105 applied to the relative shares in NMP of 1955 in Anuari statistikor, 1958, p. 134 as under: Transport and communications, 1.8 percent $\times$ 4.56; trade and catering, 7.0 percent $\times$ 3.75; other "productive," 0.7 percent $\times$ 3.45. It was assumed that the 1970 share was the same as 1969 and was applied to the 1970 aggregate of 881,000,000 leks shown in table 1-1. Kosovo data are official Yugoslav estimates from Statisticki godisnjak, 1975, tables 204-3 and 204-4 except for import surplus, the national entry for which was allocated to Kosovo. The "additional resources" provided to the Kosovo budget in 1970 were 396,000,000 leks (*ibid.*, 1971, p. 459). The actual import surplus from abroad was not published: Kosovo exports in 1973 were 768,000,000 leks but imports are not published.

## II. PLANNING AND MANAGEMENT\*

### A. Albanian Planning, 1945-1965

This section discusses the development of the contemporary Albanian economic planning system in terms of attempts made by the PLA since 1945 to establish a set of system rules which would yield desired economic outcomes. It is argued that the PLA leadership has maintained three major goals throughout its period in power and that the economic system today is the direct product of attempts to meet these goals subject to various constraints. These aims are to remain in power, to achieve the fastest possible rates of growth, particularly in industry, and to ensure that the PLA has the strongest possible direct influence on all economic outcomes. A major constraint on the first goal has been the PLA's determination to enter into external economic relations only when it has been convinced that its power to make its own decisions on domestic matters would be unimpaired. The policy aspects of these issues are considered at length in section IV and in Part III of this volume in the paper "Trade and Aid in the Albanian Economy."

By the time the PLA had come to power in Albania in 1945, the leadership had already formulated the basis on which planning methods were to be elaborated in the future. The argument was for central planning of the economy with tight control over the operation of the law of value—that is, the role of commodity-money relations—in the state sector.<sup>28</sup> To the extent that this condition would be fulfilled by Stalin's classic Soviet model the PLA intended to introduce the complete system of plan indicators as soon as possible. However, they faced unique environmental constraints which precluded the immediate establishment of so complex a system in the country. First, Albania had virtually no industry to plan, but what did exist was spread thinly in small plants across the country. Second, the low level of education of the population meant that there would have been insufficient people to man a strong central bureaucracy. Finally, although the PLA leadership wanted a powerful state economic administration, it was already arguing against its action as an "excessive or restrictive bureaucracy", suggesting that "the broad masses should take part in it on a large scale".<sup>29</sup> Hoxha was probably already

\*This section was prepared and written by Adi Schnytzer. See end of section for tables related to section.

<sup>28</sup> E. Hoxha, *Selected Works*, Vol. I, Tirana, 1974, p. 669.

<sup>29</sup> *Ibid.*, p. 671.

aware at this early stage that since he came to power without Soviet backing and was not happy about a Yugoslav presence in Albania, his survival as PLA chief would only be possible if he used his initial popular support as leader of Albania's liberating army to consolidate his power base. To this extent it might have proved imprudent to attempt to rapidly restructure a society recently ravaged by war. The measures actually taken to establish the classic Soviet model in Albania may be summarised as follows.

Nationalisation of all public utilities and foreign-owned capital was the first step in the post-war reconstruction programme. This was completed in 1946 and was followed in the same year by the nationalisation of domestically-owned means of production and foreign trade. By early 1947 what little there was of Albanian industry was in the hands of the state.<sup>30</sup> These measures allowed the State Planning Commission—which had been given its autonomy from the Economic Council and made directly subordinate to the Council of Ministers a year earlier—to draw up the country's first national plan, the nine-month plan of April-December 1947. This plan is reported to have been relatively simple in the sense that it covered only the manufacturing, mining and agricultural sectors of the economy and that only output targets for a small number of goods were detailed in the plan. These targets were given in physical rather than monetary terms and global indicators such as total industrial production or its rate of growth were not planned.

At the enterprise level 1947 saw the introduction of the Soviet autonomous accounting system *khozraschet*. Having instituted this "system" the Albanian planners were able to draw up a more sophisticated plan for 1948 than had previously been possible. Whereas the 1947 production plan was made up of selected output targets in physical units, the new plan provided more detailed specifications for the enterprise, material balances and norms of input utilisation being used in plan formation for the first time.<sup>31</sup> In 1947 investment had been undertaken as various projects required it, whereas in 1948 an attempt was made to plan capital investment for projects ranked according to planners' preferences. In addition to the more complex planning of 1948 the Albanian government introduced various organisational practices borrowed from the Soviet Union: the most important among these was the introduction of socialist emulation campaigns.<sup>32</sup> At the same time the government was in the process of drafting a five-year plan which, however, never came into being due to conflict with Yugoslavia and it was not until 1951 that the First Five-Year Plan was launched. It was drawn up essentially as material balances for a limited number of commodities and until 1956 planning remained at this simple level.

However contrary to the Party's stated aims the state administration had expanded very rapidly. So much so, that by 1953 "such an apparatus weighed heavily on the people's economy, weakened its management and opened the road to bureaucracy".<sup>33</sup> This led in the same year to a scaling down of the state administration and mass organisations by 30 per cent, those losing their jobs being transferred

<sup>30</sup> N. E. Boçari, *Shtetëzimi i mjeteve të prodhimit në R.P.Sh.*, ("Nationalization of the Means of Production in P.R.A."), Tirana, 1973.

<sup>32</sup> *Ibid.*, p. 104.

<sup>33</sup> *History*, p. 351.

to industrial and farm work. While the official reason given for this move may have some validity, it should be noted that similar changes took place elsewhere in Eastern Europe at the same time implying that Soviet policy may have been an important factor. Further, it is possible that the PLA wished to remove politically undesirable people from the hierarchy simultaneously providing industry and agriculture with additional workers.

In 1956, a money balance of household incomes and expenditures was established and national product by origin was computed.<sup>34</sup> The level of planning in Albania during the Second Five-Year Plan (1955-60) was raised annually until by 1959 the complete Soviet system of plan indicators had been adopted.<sup>35</sup>

The internal organisation of industrial enterprises was as highly centralised as the economy as a whole. It was based on the concept of "one-man leadership" (*udhëhegje unike*), and in the financial sphere on *khozraschet*.<sup>36</sup> In terms of the Chinese notions of "expertness" and "redness" the former reigned supreme. From the viewpoint of economic decision-making power, the enterprise director was completely under the control of the relevant ministry or the Executive Committee of the People's Council. Workers' interests were supposedly in the care of the Trade Union organs, whilst the grass-roots Party organisations were responsible for the ideological and political education of the working class.

It should be noted that neither the death of Stalin nor his denunciation by Khrushchev in 1956 had had any immediate implications for the practice of economic planning in Albania. The position of the worker in the Albanian economy remained, until 1965, as it had been in 1959. He had no effective part to play in enterprise decision-making and had to rely on the trade union organisation to protect his material interests. Neither was there any significant change in the overall spread of decision-making power in the economy, the shift in allegiance from the Soviet bloc to China having had no apparent impact in Albanian thinking.

However, by 1965 it had become clear that the Albanian leadership was not satisfied with the outcomes generated by the economic system.

The Third Five-Year Plan target for global industrial production was 97 percent fulfilled.<sup>37</sup> Taking into account the economic difficulties caused by the Soviet Union's economic blockade, it would seem that the industrial sector of the Albanian economy had performed well over the period 1961-65. However, it should be recalled that following the split with the Soviet Union in 1961 there was a drastic downward revision of plan targets and, as the discussion in Section III shows other sectors of the economy fared less well than industry. Thus, under admittedly difficult environmental circumstances, the classical Soviet model of economic administration was not producing economic growth rates to satisfy the leadership. More seriously, it has been suggested that economic failures were "a major factor in triggering off the unrest that began to spread through

<sup>34</sup> M. C. Kaser, "Albania", in H. Höhmann, M. Kaser and K. Thalheim, *The New Economic Systems of Eastern Europe*, London, 1976, p. 253.

<sup>36</sup> I. Elezi, *Bazat e shtetit dhe të së drejtës së R.P.Sh.*, ("The Basis of the State and Law in P.R.A.") Tirana, 1959, p. 191.

<sup>37</sup> Dokumenta Kryesore PPSH ("Major Documents of the PLA"), Vol. V, Tirana, 1974, p. 207.

Albania during 1965 and 1966".<sup>38</sup> In other words, Enver Hoxha's position as leader of the PLA was in jeopardy and this, probably more than any other factor indicated the need for change.

The existence of various bureaucratic disfunctions in the state apparatus, notably "excessive memos, unnecessary reports and countless documents" was noted in the Albanian press in 1965.<sup>39</sup> An unsigned article in *Zëri i Popullit* also hinted at the possible existence of disguised unemployment in the state sector of the Albanian economy.

When asked why the Ministry of Agriculture continually requested useless information, "after a slight hesitation an old specialist said, 'If one abolished unnecessary forms, many employees of the Ministry would be idle'".<sup>40</sup>

There is also evidence to suggest that the administration of enterprises was rather inefficient, absenteeism being very high.

Thus, for example, . . . absenteeism without reason in 1963 in Durrës Port amounted to 8.8 per cent of work time. By September 1965, that is, during an eight month period, the economic enterprises in Durrës district has lost more than 40,000 days of enterprise work potential. In counting the number of days lost, we estimate a loss of 100 workers per day whose production, had they worked, would have been valued at more than 8 million new leks. It is obvious that the loss of work hours in some enterprises has resulted in an increase in wages, and as a result, an increase in costs.<sup>41</sup>

Although it is not specified, the increases presumably refer to wages and costs per unit of output, the implication being that workers are paid even when they do not report to work regularly. It seems reasonable to argue that the extent of absenteeism in Albanian enterprises was one of the factors influencing the government to increase party and trade union influence at the grass-roots level in late 1965.

The poor quality of output and inefficient utilization of inputs were also criticised at the time.<sup>42</sup>

Finally, the method of evaluating enterprise performance came under fire.<sup>43</sup> First, it was argued that, while global indicators such as the total volume of production were useful in expressing the "dynamics of development", enterprise performance should be evaluated on the basis of more detailed indicators such as output mix and quality of products. The second criticism involved the use of labour productivity measured in value terms as an indicator of plan fulfilment. It was argued that using this indicator led enterprises to produce only those goods with relatively high prices and high per unit capital requirements. It should be noted that this criticism is directed at the notion of the price system allocating resources rather than at defects in the existing set of prices.

### B. *The Reorganization of the System, 1965-66*

The first signs that system rules would be changed appeared early in 1965 in press reports exhorting trade union organizations to do more educative work with the masses, not only in the form of lectures

<sup>38</sup> N. C. Pano, *The People's Republic of Albania*, Baltimore, 1968, p. 175.

<sup>39</sup> *Zëri i popullit*, December 26, 1965, p. 2.

<sup>40</sup> *Ibid.*

<sup>41</sup> *Zëri i popullit*, January 12, 1966, pp. 2-3. The 8.8 percent was doubtless an unusual case (though not abnormal in the West among dockers); since absence in East Europe is 4 percent of work day potential.

<sup>42</sup> *Zëri i popullit*, several issues late, 1965 and early 1966.

<sup>43</sup> *Ekonomia popullore*, No. 1/1966, pp. 3-12.

and conferences, but also at the work-bench. It was further argued that praise, as well as criticism, was necessary to raise the morale of the workers. The work of enterprise directors was also criticized at the time, it being suggested that they were not explaining directives to the workers. It was also argued that a director must be a "partyist" strictly following the "party-line".<sup>44</sup>

In October 1965 the PLA took a further step, apparently attempting to reduce the level of popular unrest, when its Central Committee, in conjunction with the Council of Ministers issued a call to the masses to participate in drawing up the Fourth Five-Year Plan.<sup>45</sup> In the document, it was explained that Albania was surrounded by imperialist and revisionist enemies, and was being subjected to an economic blockade and that, therefore, would have to build socialism relying on its own resources. It seemed clear to the leadership that since the workers of Albania knew best their own capabilities and probably the capacities of their enterprises, it was only possible to draw up a "just, real, mobilizing and revolutionary" plan if the workers were involved.

It was argued that investments and construction projects should be "more profitable, timely and essential". Workers were exhorted to approve plans which minimized expenses and waste and party members were reminded that their duty was to further the "ideo-political" education of the workers. The only specific change in planning introduced in the Appeal was that henceforth workers in enterprises would discuss broad plan targets, which the enterprise would use in drafting a detailed project plan rather than be sent a detailed plan from the state hierarchy.

The precise nature of these discussions and the real extent of worker participation in them is difficult to gauge although some light is thrown on the issue by an article in *Zëri i Popullit*, reporting on the November 1, 1965 plenum of the Central Council of Albanian Trade Unions.<sup>46</sup> The situation in the Stalin Textile Combine was brought up as an example of a good approach to the planning problem:

The combine management and the trade-union committee there bring out the key problems which determine the successful realization of the duties of the plan. The administrations of factories examine the technical-economic indices down to each worker and machine, they extract the results achieved by the best workers and these, along with the propagandistic work for illuminating the political and economic importance of tasks, are placed in discussion in the brigades, complexes, shifts and departments. In such an atmosphere of active, concrete and responsible work, the workers give their highly valuable ideas not only about advancing the index of the plan, but also about steps for the successful completion of it. During the discussion of the pilot plan for 1966, 613 workers spoke here. Such efforts have had an influence on the increase of the mobilization of all workers for fulfilling their tasks.<sup>47</sup>

By contrast, the draft proposals for the 1966 plan in the Shkoder district were presented to the workers by enterprise management as a *fait accompli*, trade union officials often being absent from the meetings. This situation, the Plenum emphasized, should not occur in the discussions of the Fourth Five-Year Plan. The emphasis of the change in approach to planning is clearly laid on greater propaganda efforts by the trade unions, and it is suggested that discussions in

<sup>44</sup> See, for example, *Ekonomia Popullore*, Nov. 1, 1965, pp. 3-19.

<sup>45</sup> *DK*, vol. IV, pp. 539-557.

<sup>46</sup> *Zëri i popullit*, November 3, 1965, p. 2.

<sup>47</sup> *Ibid.*

small groups—even down to brigade level—would prove more useful than large meetings: “Study on a group basis, as well as the separate discussion of the production or service plan, of labor productivity, of the capacity of the machinery of standards of use of materials, etc., would be more effective”.<sup>48</sup>

Finally, the plenum argued that only by bringing workers into the planning discussions fully, could enterprise managers be prevented from drawing up minimum production plans with inflated resource requests. Implicit in this argument is the assertion that notwithstanding—and perhaps as a consequence of—the highly centralized nature of the classic Soviet model it was not possible to ensure congruence between management and hierarchy goals. Thus, the greater involvement of workers in plan discussions may be seen as an attempt to supplement hierarchical pressure on directors with Party-led pressure from below. The plausibility of this hypothesis is reinforced by the ideological measures introduced since 1966 which are discussed later in this section.

The second series of changes in system rules involved the shift, in the middle of 1965, of artisan cooperatives and several enterprises from ministerial to local district control. While the majority of plan indicators required Council of Ministers approval at this time, the partitioning of the hierarchy prepared the way for the decentralization in economic decision-making power which was to follow early in 1966:

*Decision No. 15 of the Council of Ministers*, dated February 17–21, 1966, ‘On the Fundamental Principles of the Methodology of Planning’ outlined the changes in the Albanian planning system intended for the period of the Fourth Five-Year Plan, 1966–1970. Although the *Decision* does not appear to have been published, its contents are discussed in detail by the Albanian economist, A. Backa, who begins with a definition of the planning methodology as:

... the general criteria and special instructions concerning the drafting of plans for each activity, the special indicators, the nomenclature of indicators and the examples of preliminary plans at all levels, the route of planning and the schedules, broadly employing the averaging and balancing methods.<sup>49</sup>

After giving an outline of the development of the planning methods in Albania, Backa pointed out that the *Appeal* had revealed the need to revolutionize the planning system and described the projected changes.

There were three major steps in the system of plan formation operative between 1949 and 1966. In March of the preplan year a draft of the plan was sent from the centre to the enterprises (the ‘quota phase’). The enterprise then sent their revisions back to the centre (the ‘preliminary plan phase’) so that the State Planning Commission could co-ordinate the various plans and pass the final version on to the Council of Ministers for approval by November 15. The final approved plan was then sent back to the enterprise as law. In addition to this procedure, import and export plans were drawn up separately in June of the preplan year and revised (to co-ordinate with the state plan) in November. Finally, in the old system, quotas for imports and construction project outlays were set annually.

The new methodology simplified these procedures considerably. The quota phase of plan formation was eliminated and the remaining

<sup>48</sup> *Ibid.*

<sup>49</sup> *Ekonomia popullore*, No. 2, 1966, pp. 14–27. The following discussion draws heavily on this article.

two stages were rescheduled in the following way; in June, national enterprises and in July, Executive Committee of *rreth* People's Councils, send their preliminary draft plans to the relevant central organ. It should be noted that the plans sent by Executive Committees relate to small enterprises whose products are of predominantly local importance, and which have no planning sections of their own. Upon receipt of the preliminary plans, the various central organs process and co-ordinate their respective plans and send them to the State Planning Commission in August. During September the State plan is drawn up and approved by the Council of Ministers. Further, the import plan is now drawn up as part of the general planning procedure and figures from the five-year plan are used as guides to imports and construction project outlays, replacing the previous annual quota system.

In addition to these changes in scheduling, the *Decision* altered the nature of the plan indicator system drastically. There was a significant reduction in the number of indicators in the state plan so that only those essential for determining the main directions of economic and cultural development were included. Thus, whereas prior to the change the plan contained 550 indicators relating to industrial production which had to be approved by the Council of Ministers, the number of such indicators now dropped to 77. Unfortunately, the precise nature of these indicators is not known. Similar changes took place for all sectors of the economy, the relevant figures for agriculture being 320 down to 42 and in investment and construction 100 items require approval by the Council of Ministers where previously the number had been 500. One specific change should be noted because it had important repercussions: the banking system's control over investments was removed.

These reductions in plan indicators were accomplished by decentralising the power to make many decisions which the Council of Ministers had previously taken. The recipients of the new powers were the ministries and the Executive Committees of the *rreth* district councils. In industrial planning, only targets for major products would now be presented to the Council of Ministers in aggregate, whereas before the change these targets were disaggregated by the enterprises and were presented along with other indicators (now eliminated) such as a number of secondary products, products of local importance, technical and economic indicators for various branches, tasks for new product output, scientific research projects, prospects for the mechanisation of labour and other improvements in technology.

In the trade sector, the distribution and material and technical plans were combined, only the total sales being approved on an index by the Council of Ministers. Similar aggregation occurred in labour planning, the Council of Ministers approving only the projected totals of administrative workers and their wages, and productivity indices for industry and construction. Finally, the Council of Ministers now approves plans annually where previously it had been done quarterly.

These simplifications in the plan sent to the Council of Ministers for approval did not, however, imply a simplification in the plan itself. The enterprises were required to draw up plans which were as

detailed as before the change. The difference lay in the level of the hierarchy made responsible for dealing with the particular issues. The relative positions of the ministries *vis a vis* the Executive Committee would appear to be that generally the ministries received more power with respect to plan formation whereas the Executive Committees were expected to become more involved in ensuring plan implementation. Thus, under the old system the detailed plans, by *rreth*, for all production of national importance, transportation, trade, turnout, investment and construction, education, culture and health, were approved by the Council of Ministers. The *rreth* plans for supply, distribution of local products, the work force, productivity, wages, costs and a number of other technical and economic indicators were the competence of the relevant ministry. According to the *Decision*, the detailing of all the above-mentioned plans would be done by ministries and sent to the relevant Executive Committee for co-ordination and supervision of implementation.

The final type of change made by the *Decision* was in the method of enterprise performance evaluation. On this point, however, Backa was unclear. He states that global indicators such as the total value of output would no longer be the primary criteria for evaluation, arguing that both enterprises and ministries would be responsible for the fulfillment of plans in quantity and quality. However, Backa gave no indication of the nature of penalties and rewards associated with plan fulfillment under the new or old systems. In view of the pay cuts which were to be announced in March, 1966, it seems unlikely that material incentives predominated in the reward system. On the other hand, it is possible that the change in evaluation of enterprises was essentially an academic matter, its mere announcement being intended to influence the behaviour of enterprise directors.

Prior to a consideration of outcomes arising from these *sensu stricto* economic system rule changes, the ideological campaigns superimposed on the new planning system must be described. In February, 1966 the PLA Central Committee issued a statement noting that in response to the *Appeal* many cadres had volunteered to work in production. The *Appeal* had initiated a process of social metamorphosis whose high point was yet to come.

### C. The Ideological Campaigns

On March 4, 1966 the General Committee of the PLA issued an *Open Letter* to the population,<sup>50</sup> the immediate consequences of which included a reduction by 15,000 in the number of state administrative employees, the abolition of military ranks and the introduction of political commissars in the military units, the dispatching to the countryside of several intellectuals, managers and party officials and the replacement of an unspecified number of cadres in executive positions. There was also a reduction in wage differentials, highly paid Albanians suffering a reduction in salaries. This anti-inflationary measure has since been used on several occasions, most recently on April 1, 1976.

While it is possible that the Albanian leadership considered the reduction in state administrative employees to have been facilitated by

<sup>50</sup> *Zëri i popullit*, March 4, 1966, pp. 1-3.

the changes in economic planning resulting from the *Decision*, the crucial implication of the *Open Letter* was an increased emphasis on the politicisation of life—using again Chinese terminology, “redness” was now to be placed above “expertness”. From the workers’ point of view, it is clear that attempts had been made to bring workers closer to the process of plan determination, however the Albanian worker was still subject to a Labor Code which, though recently modified, contained penal sanctions and did little to encourage a sense of participation in the running of the economy. In September, 1966, the changes which were apparently sweeping Albanian society found their way to the worker when the new Labor Code was issued.<sup>51</sup>

Whereas the old Labor Code had 264 articles, the new one has only 63. All reference to penal sanctions against workers is gone and the new Code has a decidedly revolutionary tone. It should be noted that the role of the trade unions has changed dramatically compared with the role they formally played.

Although the Code allows them a significant consultative role, any economic decision-making power they had ever had in the past has been transferred to the state hierarchy. The mobilisation and education of workers is now seen as the major task of the trade unions and there are stipulations which allow the establishment of worker’s control commissions in enterprises. One of the articles is significant in that it attempts to discourage overtime work as a means of increasing income. Rather, the trend has been towards voluntary “overtime” work and there are many cases reported in the Albanian press of workers who have finished their jobs for the day helping in the construction of flats, schools, etc. Here, as in the case of the planning discussions, the distinction between coercion and persuasion, and desired and actual implementation, are difficult to make.

Although the 5th Congress of the PLA took place in November, 1966, only a month after the appearance of the new Code, no mention was made of it by either Enver Hoxha or Mehmet Shehu in their respective speeches. There was, however, continued reference to workers’ participation in planning, the revolutionisation of life and the on-going fight against bureaucracy.<sup>52</sup>

In a speech made on February 6th 1967, Enver Hoxha stressed that in solving problems of organisation which arise in the state enterprise

. . . the only correct and complete judgement is the check up of the collective which verifies and should verify the case. This means “the control by the masses” and “policy of the masses” all without exception should submit to the judgement of the masses on their work and conduct in society. The communists should submit to a twofold control to that of the Party, and to that of the masses.<sup>53</sup>

When new directors or other senior or technical staff were appointed to an enterprise, Hoxha argues the new man should go before the workers’ collective, and give “a frank account of himself so that the masses may pass judgement on him.” Further, the new employee or director should be told that if he blunders ‘we will pull your ears whereas if he keeps making mistakes

We will throw you overboard and bear well in mind that there is no one who can help you; the Party is ours, the regime is ours, it is we who are in power, it is the dictatorship of the proletariat which reigns. . . .<sup>54</sup>

<sup>51</sup> *Përmbledhëse e përgjithshme e legjislacionit në fuqi të R.P.Sh* [1945-1971], (“General Collection of Legislation in Force in P.R.A.”), Tirana, 1971, pp. 89-100.

<sup>52</sup> *D.K.* Vol. V, pp. 60-227 gives the proceedings of the Congress.

<sup>53</sup> E. Hoxha, *Speeches 1967-8*, Tirana, 1969, p. 31,

<sup>54</sup> *Ibid.*, pp. 33-34.

With respect to displays of bureaucratism the solution rests again with the workers.

. . . the labouring masses should by all means and without hesitation knock down the director of this type or any other functionary of this kind, whoever and of whatever rank he may be in the Party or the government.<sup>55</sup>

One mechanism whereby this workers' control would take place would be in the wall bulletin. Albania, along with all the other socialist economies of Eastern Europe, had always used wall posters in their state enterprises, but Hoxha gave his opinion of these and was explicit about the need for changes.

. . . do away with the existing and very ridiculous wall bulletins and turn them into revolutionary wall bulletins which will help revolutionary education. Do away with these wall bulletins with their editorial boards of opportunist scribblers who uphold the dignity and authority of the director and of themselves at the same time, and that everyone write what he thinks of work and of the people in bold face letters and without fear.<sup>56</sup>

Hoxha also stressed the need for improving the circulation of cadres through the economy, all administrative and office workers should spend no less than 100 days of every year in production work—the period was shortly afterwards reduced to one month—and directors of enterprises should be changed regularly to prevent their “bureaucratic stagnation.”

The implications of Hoxha's speech for workers' control were apparently significant. In several enterprises workers were reported to have been instrumental in solving problems of plan realization where state administration had failed.<sup>57</sup>

In addition to these spontaneous displays of workers' control, Hoxha's speech also allegedly gave rise to

. . . initiatives for the establishment of a revolutionary workers' control by organizing various control groups to deal with all the economic problems related to the successful implementation of the plans, and the regulation of all work in enterprises. Some of these are control groups to check the quality of products, the maintenance and exploitation of machinery and the material inventory of the enterprise, etc.<sup>58</sup>

The trade unions were responsible for the organization of elections to the commissions ensuring that candidate workers were ideologically and politically motivated. However, once elected, the commission was to be free to examine all aspects of the functioning of its enterprise, though its powers were advisory. Any significant problem it encountered was to be communicated to the entire collective of the enterprise, and management was expected to find a solution. The trade unions and party organs within the enterprise would doubtless be instrumental in applying pressure to the enterprise administration to ensure the effectiveness of the workers' control.

It is possible to draw several conclusions on the basis of the foregoing discussion. Firstly, it is difficult to gauge the extent to which Hoxha was serious when he asked workers to criticize freely. However, even if he should be taken literally, the existing superior-subordinate relationships which had up until then been officially endorsed could not be expected to change rapidly. Second, if the reports concerning improvements in efficiency resulting from the action of workers' control are true—and there is no reason to doubt them—it is clear that

<sup>55</sup> *Ibid.*, pp. 50–51.

<sup>56</sup> *Ibid.*, p. 55.

<sup>57</sup> *Zëri i popullit*, July 5, 1967, p. 2.

<sup>58</sup> *Ibid.*

the organization of inputs to the production process in Albanian enterprises was far from optimal. It is also an indication that the changes made in the planning system in 1966 were not yet contributing significantly to enterprise efficiency. Third, it can be seen that the functions of the workers' control commissions were two-fold. In the first place, the commissions were organs of control, ensuring that both the administrators and workers' collectives of the enterprises worked towards consistently fulfilling plans. Their second function—integrally linked with the first—was to motivate fellow workers.

It is clear that the movement for workers' control in Albania may be viewed as a logical extension of the attempts to involve the workers in planning. The distinction between these two increments of perceived participation is that, whereas the discussion of plans was intended for all workers, control functions were limited to the elected commissions. That these commissions began finding difficulty in their work became evident at the beginning of 1968. An article in *Bashkimi*<sup>59</sup> noted that over a nine-weekly period in 1967 egg breakages had not been entered as a loss in the accounts of the Mat district cooperatives. The workers' control commission was criticized for failing to properly safeguard communist property. However, the most common and not unexpected problem faced by the commissions appeared to be interferences from administrator;

... the efforts of some bureaucratic administrators to channel the control of workers' commissions into a bureaucratic framework according to "Rules and Regulations" only shows their fear of the masses' revolutionary momentum. There is no other way to explain the tendency of some administrators to "institutionalize" and to keep the workers' control under "control".<sup>60</sup>

Shortly after this revelation of bureaucratic hindrance the nature of workers' control in Albania was changed, taking on the form it has retained until the present time. The change arose as a consequence of a speech made by Enver Hoxha on April 19, 1968, entitled "Working Class Control".<sup>61</sup> In it, Hoxha criticized the workers' control commissions as having yielded no positive results: "not only this, they have become bureaucratic elements, they have eliminated the grass roots control, they have replaced the trade unions committees, people from the administration have entered them as heads of the commissions" and this led to "marked manifestations of revenge towards the workers' criticisms." Consequently, Hoxha argued, while commissions composed entirely of workers might provide some measure of improvement, it would be best if the commissions were replaced entirely by "direct workers' control".

Thus, committees of worker control would henceforth be elected on an ad hoc basis as particular problems arose and their membership would be limited to workers engaged directly in production.

The change in the nature of workers' control in Albania may also be explained in terms of the hypothesis formulated earlier; namely, that if this type of control was primarily intended to put pressure on the enterprise director during the period of plan implementation—the plan having been drafted with the assistance of the worker participation mechanism—allowing representatives of management to sit on the commissions would possibly dilute their impact. The above-cited attempts by management to "control" the commissions lends weight

<sup>59</sup> *Bashkimi*, January 24, 1968, p. 2.

<sup>60</sup> *Zëri i popullit*, February 22, 1968, p. 2.

<sup>61</sup> E. Hoxha, *op. cit.*, pp. 221-250.

to this conjecture. Hoxha's proposal that control groups should only be elected when necessary might be expected to increase the flexibility of local party organs while limiting the possibility of undesired liaison between a permanent commission and management. However, the ultimate success or failure of workers' control must rest on the extent to which workers are motivated to act as a pressure group on management. The reductions in high salaries, the insistence that cadres participate in physical production and the constant propaganda impact of the mass media and the education system may be expected to operate in favour of the achievement of the PLA's goals, but there is insufficient evidence available to draw any concrete conclusions on this issue.

#### *D. The Outcomes of the New System*

The Politbureau report<sup>62</sup> to the Sixth Plenum of the PLA Central Committee of September 27, 1968 provides evidence that the leadership was not satisfied with the outcomes of the ideological campaign. In the report Ramiz Alia clarified the ideological motivation for the measures which had been carried out and pointed out areas in which the "revolutionization" of society was encountering problems. With respect to ideology Alia noted that:

... socialist revolution is uninterrupted evolution. It doesn't end either with the seizure of the reins of state or with the building of the economic base of socialism. The whole process of socialist and communist construction is the process of developing and deepening proletarian revolution in the political, economic, and ideological fields. Interrupting the revolutionary struggle, stopping the revolution half way is fatal to the destiny of socialism. The fact is that the class struggle, the struggle between the socialist and capitalist ways continues throughout the period of transition from capitalism to communism. This is the fundamental contradiction all through this period.

The experience of what happened in the Soviet Union and elsewhere indicates that the danger doesn't come from the exploiting classes and their survival alone, from their counter-revolution by violence, not from external imperialism from its armed aggression but comes from bourgeois-revisionist degeneration whose base lies precisely in the "dregs" of the old capitalist society which are still kept in socialism.<sup>63</sup>

The problems being encountered in Albanian society were divided into four types. Firstly, there was the problem of bureaucracy as defined by disfunctions in the relationship between cadres and workers.

Failure to set and continuously perfect these relations along correct socialist lines will inevitably lead to the emergence of bureaucratism and to the degeneration of cadres who, from being servants of the people gradually turn to a new bourgeois class which follows a bourgeois policy and uses its power to secure a privileged position for itself and to hold sway over the people. This sets up relations of oppression and exploitation between this stratum and the masses. Social ownership gradually loses its socialist nature and turns into ownership of the state capitalist type.<sup>64</sup>

Alia argued that the problem would only be solved if the cadre circulation and the participation in physical production policies were properly implemented and indicated that resistance was being encountered to the scheme.

Second, technocratism, economism and intellectualism as bureaucratic disfunctions would need to be overcome. Here Alia was referring to intellectual-worker relations, arguing that in the training of experts,

<sup>62</sup> *Zëri i popullit*, October 3, 1968.

<sup>63</sup> *Ibid.*

<sup>64</sup> *Ibid.*

priority should be given to ideological over technical education. The basis for concern over intellectuals is similar, though not identical with that for cadres. The problem arises

. . . not because of their nature, but because of their tendency to detach mental from physical labour, of their position and the role they play in leading and organizing work, of the individual nature of their work are the intellectuals susceptible to alien bourgeois and revisionist viewpoints, ideology, politics and ethics, are they inclined to detach themselves from the masses, to overrate their role, ability and talents, to place themselves above the masses, to slip into postures of egotism and intellectualism, self-conceit, to consider themselves the only force capable of directing and leading. Therefore it is here that a very important area of the class struggle lies.<sup>65</sup>

Third, Alia raised the problem of conservation, noting both economic and political manifestations. He cited failure to properly implement measures for the increased mechanization of production processes in the Albanian economy which had been outlined by the Third Plenum of the CC of the PLA (13th–14th Oct. 1967). He accused managers of conservatism in refusing to implement labour saving changes in technology. In the political sphere Alia argues that conservatism had led to opposition to the appointment of young cadres in various positions throughout the society. In this connection, he asks:

If we fail to train and promote new cadres right away, then, when shall we do it? Our comrades must never forget that when our Party and People trusted them for the first time with posts of great responsibility, they weren't only very young in years but didn't have that culture and those skills the new cadres, carefully educated by the Party and arked with its ideology and a wide range of professional skills boast of today: . . . The struggle against conservatism is a long and perpetual one. It will never end because our society keeps developing, some things always spring up and grow while others become obsolete and should be discarded.<sup>66</sup>

Fourth, Alia spoke of the need to fight the tendency to be motivated by personal interest and place general above personal interest in everything and at all times.

It is noted that this tendency is not manifested only in the material shoppers, in the running after money and a fat salary, after privileges and material advantages, in the tendency to contribute as little as possible and wrest as much as possible from society, in occupying a comfortable post in town. It is manifested in a thousand and one more forms extending also to the moral features envolving one's own character like egotism and individualism, envy and personal ambition, intrigues and lies, career-seeking and servility, arrogance and self-conceit, comfort and ease and personal glory and familiarity and nepotism, acquiescence and apathy, localism and partiality and so on and so forth. This means that there are many problems, there is a whole field of action to imbue the people with the norms of communist ethics and to educate them in the spirit of placing the revolution above everything else.<sup>67</sup>
